**(3) Ligation of the Deep Veins—Resection** Four dogs were used and one-half centimeter of bone resected from corresponding levels of the fibulas on both sides in two, and one-quarter centimeter of bone removed in the other two animals. The deep veins in the left leg were exposed, ligated distal to the point of entrance of the saphenous vein into the common femoral, and divided. Roentgenograms were taken from time to time and showed that union took place on both sides at about the same time. If there was any difference in the amount of union, it was more substantial on the experimented left leg. (In removing the bones for study in three of these animals, there was motion on the right in one instance and a fracture of the callus in a second.) The callus formed on the left fibula (deep veins tied) was considerably larger than on the control right leg in two or three animals in which the bone was removed and exactly the same size in the third which had probably gone too long to reveal the difference. The X-rays taken at a certain stage (4-7 weeks) showed a larger callus formation on the left side in all four instances.

**(4) Ligation of the Deep Veins—Fracture** Two dogs were subjected to exactly the same conditions as in the resection experiments except that a simple fracture was made. Union occurred on both sides equally, but there was considerable variation in the size of the callus. In one case it was larger on the left than on the right and the reverse in the other case. Difficulty in controlling overriding makes the simple fracture a much poorer experiment as this probably accounts for the differences in these cases.

**(5) Ligation of Both Common Femoral Artery and Common Femoral Vein Resection—Fracture** One half centimeter of bone from the

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls, N. Y., May 11, 1927.

up to the one who has shown up regularly year after year

In all these cases the blood reaction has remained constantly negative up to and including the last examination we have been able to make

The blood reaction of two of the thirty-three cases just mentioned was positive at the end of the first six months. Both of these cases are instructive. The first applied for treatment in the fall of the year. He presented at that time a typical chancre situated on the penis. The dark-field examination showed spirochetæ in abundance, while the reaction of the blood was negative. He was told that he had syphilis and that he would require six weeks of treatment at once. He was also given the initial injection of mercury. Unfortunately, as subsequently transpired, he was also told of the negative reaction of the blood, hoping, of course, to reassure him. The result of this little piece of humanity and sympathy was disastrous. We saw nothing more of him for three months, when he returned presenting a profuse roseola, enlarged glands, and a four plus Wassermann reaction. The chancre had healed and there was no sign or history of any other genital or extra-genital sore. This man's blood, after two years, still gives a four plus Wassermann test, in spite of three intensive courses of treatment. We have had two other similar cases since this report was begun with this difference, that they have responded better to treatment.

The second case received several injections of arsphenamin and mercury, but quit early in the course. He returned within the first six months for a blood test. This proved to be four plus, but we have seen nothing of him since he received the report and we know nothing of his subsequent history.

## CONCLUSIONS

That every initial lesion does not present the appearance of a typical Hunterian chancre and that the dark-field will bring to light many cases of syphilis that otherwise would be overlooked until too late.

That extra-genital lesions, whether primary or secondary, are exceedingly contagious and that the saving of a few hours or even a few minutes, in establishing the contagious character of a lesion on the hand or about the mouth, may prevent most disastrous or even tragic results.

That urethral chancres are far more common than generally believed and that every case of urethral discharge should be regarded as a possible symptom of beginning syphilis, even if the diagnosis of gonorrhoea is positively established.

That in view of the fact that the disease seems to have been eradicated in 94 per cent of our cases whose Wassermann test was negative while the dark-field was positive, a heavy responsibility rests upon all institutions and physicians who expect to diagnose and treat syphilis and diseases of the skin to see to it that a dark-field examination is made of every suspicious lesion as a routine procedure.

Also that where possible these examinations be made by a competent and experienced microscopist paid for the purpose, and not left to the hurried and perhaps careless or inexperienced. In support of this statement I invite your attention to the fact that the Surgeon General of the Public Health Service constantly urges all Marine Hospitals and other relief stations to make careful dark-field examinations.

## STANDARDS OF MEDICAL NEWS

The NEW YORK STATE JOURNAL OF MEDICINE has evolved standards for the articles in its department of New Notes

Does the item deal with an important medical problem?

What plans were adopted for its investigation and solution?

What was the result?

Will the experience that is described help other physicians to deal with their local problems?

These standards exclude the publication of isolated facts usually called personal, whether of individual doctors, or institutions, or organizations, for these items merely give pub-

licity to individuals. Yet when an item records a progressive plan or idea, the Journal will give full publicity to its originator or promotor, but the individual will be subordinated to the idea for which he stands.

News of a County Society or District Branch or the State Society will be considered to conform to the standards of this Journal, for the activity of any component of the State Society affords a precedent and example for the guidance of other societies.

These standards have been observed during the twenty-six years of the existence of the Journal, and are now restated by the direction of the Committee on Publication.

fibula was removed on both sides at the same level in one dog and a simple fracture of the bone was made at corresponding points in another. In both these animals the common femoral artery and the common femoral vein were ligated and divided proximal to the branching into saphenous and deep systems. Union took place at the same time on both sides. The size of the callus was variable on the two sides.

*Discussion.*—The results of these experiments seem to indicate that the control of callus formation is regulated by changes in the venous circulation. It would appear that a partial blocking of the venous return from the leg by ligation of the saphenous vein is followed by a delay in osteogenesis in a resected or fractured bone. A blocking of the deep veins, however, which causes a shunting of the venous blood through the capillary bed of the foot and by collateral veins to the saphenous system is not accompanied by any such delay, the healing in such a case being as rapid as on the control side. In addition to this the callus formed at a certain stage in the process tends to be larger than on the normal side. A great many questions arise as to the significance of these findings and there are indications for many experiments yet to be performed. Is the phenomenon one of the disturbance in the nutritional relations? It may be argued that ligating the deep veins raises the pressure in the deep system below the ligature and prevents the arterial blood from furnishing nutriment to the bone cells by back pressure. If such were the case non-union would be looked for but instead there appears to be equally rapid union and more callus. An additional answer to this argument is the fact that union takes place equally well even after the artery is ligated. Is the change one of the blood chemistry? This portion of the experiment has not been investigated as yet. The determination of the  $P^H$  of the blood in the common femoral vein after ligation of the saphenous vein, however, has been determined twice daily over three days as an index. The colorimetric method as described by Hastings and Sendroy was used. No appreciable change was made out in a comparison with the blood from the normal side, the readings being constant at 7.6.

The determination of the  $P^H$  from the saphenous vein after ligature of the deep system in comparison with the blood from the saphenous on the normal side showed no appreciable change. These determinations were made twice daily over a period of two days. It is probable that no change in the  $P^H$  can be demonstrated in the blood, as it is a tissue which has great power of restoring the acid-base equilib-

rium. Determinations of the  $P^H$  of the tissues of the extremities are much more important. This was attempted in the rat by use of the outlying acidosis method of Rous with phenol red as an indicator. Other indicators of a wider range of variation are under trial.

A change in the  $P^H$  might conceivably make a difference in the deposit of calcium and other salts as certain work seems to indicate. A determination of the calcium-phosphorus ratio of the blood from the different sides under the different conditions of the experiment must be undertaken.

The blood volume flow from the common femoral vein was determined to be about 24 cc. a minute in one dog. When the saphenous vein was constricted, the flow from the common femoral was reduced to 18.5 cc. a minute, but when the deep vein was constricted only 5 cc. flowed through the common femoral vein in one minute. This was the average of several determinations in which an almost constant ratio was maintained. This means that there is roughly three to four times as much blood coming from the leg by the deep system as through the superficial. This point needs further clarification, especially the late changes in the volume flow after ligation of the different veins.

The differences in the size of the callus were determined by actual weighing of symmetrically removed pieces of bone. Determinations of the amount of water, fat, organic residue and ash were made but the data is not sufficient to be conclusive. The ratio of water to the other constituents, however, is constant in comparison to the normal side, showing that the increased size is not due to edema of the tissues.

Burrows maintains that the essentials for growth are a retarded circulation and a diminished oxygen tension. Under these conditions a growth substance given off by living cells accumulates and stimulates further growth. Under conditions of a normal circulation this substance is swept away into the general circulation and destroyed. Tying the saphenous vein would increase the flow of blood through the deep venous system preventing the accumulation of such a growth promoting substance and delayed union would result. Tying the deep system, on the other hand would give all the favorable factors for growth and an enlarged callus would result. If the repair rate were not already at its maximum, a difference in rate might be observed, but it is probable that any repair process of the body proceeds at maximum speed. The experiments cited in this paper tend to confirm Burrows' theory of growth.

3 They shall secure the cooperation of the local Tuberculosis or Parent-Teachers' Association in getting parents to bring the babies to the clinics, and looking after them, and taking them home

† The lay workers shall follow up the defective cases and aid the mothers in applying

the treatments—food, hospitalization, operations, and whatever else is prescribed by the doctors

If the doctors once decide to practice public health, they will find a way to secure the co-operation of the lay organizations, and to lead them in forming their plans

## RESPONSIBILITY FOR HEALTH

The responsibility for health conditions of all kinds rests primarily with physicians, for it is the medical profession that investigates the causes of ill health and disease, and develops the means of cure and prevention

When physicians have developed a health measure, the next step is its adoption by the people. The maintenance of constant health, like that of physical strength, or beauty, or courtesy, or morality, requires active watchfulness and effort by the one seeking it. No one expects the pastor to "compel" people to be good, neither should any one expect the doctor to "make" people well. The doctor lays out and builds the road to health, and acts as guide to those who seek it, but he cannot compel people to follow the road, neither can he carry them. The lay health worker persuades his fellows to walk the road to health, and provides the means of transportation, subsistence, and refreshment to those travellers who need them.

Laymen cannot build the road to health, neither can physicians advertise it and secure patrons for it. Both physicians and laymen

have a mutual need for each other, in designing and operating the road.

Concretely the leaders in the practice of public health are organizations of physicians, and organizations of laymen. A doctor treating only the sick who hire him will reach only a small proportion of the people of a community. An organization of doctors, working with an organization of the people, is necessary in order to reach all the people in a community. The civic duty to improve health rests equally upon the people and upon the medical profession.

The concrete representation of the people is the lay health organization,—usually the County Tuberculosis Committee. The concrete representative of the medical profession is the County Medical Society.

While the individual physician in the past has disclaimed a personal responsibility for the practice of public health, yet now he realizes that he himself is the medical profession. The fundamental act by which he may satisfy his conscience and practice public health is to support the leaders in his county medical society in their activities.

## LOOKING BACKWARD

### THIS JOURNAL TWENTY-FIVE YEARS AGO

*Uniting the Two State Medical Societies*—This Journal for November first, 1902, contains a four-page report of the first steps taken to unite the two State Medical Societies,—the Medical Society of the State of New York, and the New York State Medical Association which had existed since 1883, as described by Mr. Stryker on page 1207 of this issue. The report consists principally of letters which passed between the conference committees of the two societies. The correspondence began on February 5th and 7th, 1902, with two letters from Dr. F. C. Curtis, of Albany, Secretary, stating that the Medical Society of the State of New York had appointed a conference committee consisting of the following members: Dr. Henry L. Elsner, of Syracuse, Dr. A. Jacobi, of New York, Dr. A. Vander Veer, of Albany, Dr. A. M. Phelps, of New

York, Dr. George Ryerson Fowler, of Brooklyn.

The Council of the New York State Medical Association met on February 7th and appointed as a conference committee Dr. E. Elot Harris, chairman, and Drs. William H. Biggam, Emil Mayer, Parker Syms and Frederick Holme Wiggin, to which committee the president is added as a member ex-officio.

Meetings held in the New York Academy of Medicine, on March 19 and April 18, decided on the form of a bill to be introduced in the next Legislature authorizing the union of the two State Societies into the single one that now exists.

The report stops at this point with the outlook favorable to the speedy union of the two societies, but over three years were to elapse before the various opinions of the members could be harmonized and the union effected.

## THE LAY HEALTH ORGANIZATION AND THE MEDICAL SOCIETY

Volunteer health associations composed principally of non-medical members, have been organized in order to do those forms of health work which physicians were not undertaking on a large scale. This JOURNAL has frequently referred to the trinity of health forces—the physicians, the departments of health, and the lay organizations. It was inevitable that there should be an overlapping of the fields of activities among these three groups of public health workers, and it was also inevitable that each of the three groups of workers should gradually find its own peculiar field of activity, distinct from the fields of the other two. The processes of standardization of methods and the recognition of fields of activity have progressed far between doctors and health departments, and to a less degree between doctors and the lay organizations.

When a group of lay health workers is mentioned in New York State, a physician immediately thinks of one of two organizations

- 1 The State Charities Aid Association,
- 2 The Parent-Teachers' Association

Each organization has local groups in nearly every county. That of the State Charities Aid Association is the County Committee on Tuberculosis and Public Health that is supported by the sale of Christmas Seals. Local Parent-Teachers' Associations exist in some of the cities and larger villages, and only seldom in rural sections. Both of these organizations are essential not only to the people, but also to physicians in their endeavor to do their duty to the people in the practice of public health and civic medicine.

Experience shows that a county medical society cannot carry out a program of public health without the cooperation of lay health organizations, and the reverse is also true, that lay organizations cannot carry out their programs without the active cooperation of the physicians.

Why does each group of health workers need the other? Because public health work involves two groups of activities

- 1 Medical,
- 2 Social, including the educational and the economic phases of practice

Curative medicine consists of 90 per cent medical service and 10 per cent social service. When sickness is actually present, everybody is anxious to practice the virtue of charity and to assist those in need of help.

The practice of public health and civic medicine is largely preventive, and consists of only 10 per cent medical, while 90 per cent of its activities are of a social nature. Any one who practices preventive medicine will give only 10 per cent of his time to medical work, while he must give 90 per cent of his time to

work of an educational, economic and social nature.

This same proportion of activities holds true in the practice of curative medicine, if everything that is done for a patient is considered. A doctor, for example, gives an hour of his time to the patient daily, a nurse gives all day, the family of the patient subordinate their lives to his service, and if the patient is poor, the charitable organizations and churches and visiting committees spend hours of time upon the case. If all the time given to those activities is considered, the total activities in the practice of clinical medicine will be found to consist of 90 per cent non-medical and 10 per cent medical services, as in the practice of preventive medicine.

When a person is sick, every activity centers around the medical service, and the doctor is accepted as the commanding officer whose slightest wish must be obeyed.

The practice of preventive medicine consists largely in averting dangers which are set forth in tables of dry statistics. Much educational work will have to be done before the people will be eager to demand that measures for their own health protection will be adopted.

The object of any public health work is to apply medical knowledge in the prevention of disease. Practicing physicians know what medical science can accomplish—its possibilities and its limitations. They are also the best judges of the efficiency of proposed health measures. They are especially qualified to judge of the practicability of measures that are proposed by lay organizations, and they deprecate the issuance of promises that are too rosy for realization. The lay health organizations need the direction and guidance of the physicians, especially in their local programs.

The actual practice of all forms of medicine—preventive as well as curative—is the exclusive function of physicians. The work of lay organizations is the development of means by which the patients may avail themselves of the medical services of physicians. Physicians can scarcely practice preventive medicine without the help of lay organizations. Each group is complementary of the other, but it must be remembered that the work of lay organizations is the *means*, while that of physicians is the *end* of public health work.

These principles may be applied in actual practice. The steps in the application may be illustrated as follows:

- 1 The physicians shall decide to practice some form of public health and civic medicine, for example, to hold a child welfare clinic.

- 2 They shall make specific plans for the clinic, the time, the place and the appointment of examiners.

3 They shall secure the cooperation of the local Tuberculosis or Parent-Teachers' Association in getting parents to bring the babies to the clinics, and looking after them, and taking them home

4 The lay workers shall follow up the defective cases and aid the mothers in applying

the treatments—food, hospitalization, operations, and whatever else is prescribed by the doctors

If the doctors once decide to practice public health, they will find a way to secure the cooperation of the lay organizations, and to lead them in forming their plans

## RESPONSIBILITY FOR HEALTH

The responsibility for health conditions of all kinds rests primarily with physicians, for it is the medical profession that investigates the causes of ill health and disease, and develops the means of cure and prevention

When physicians have developed a health measure, the next step is its adoption by the people. The maintenance of constant health, like that of physical strength, or beauty, or courtesy, or morality, requires active watchfulness and effort by the one seeking it. No one expects the pastor to "compel" people to be good, neither should any one expect the doctor to "make" people well. The doctor lays out and builds the road to health, and acts as guide to those who seek it, but he cannot compel people to follow the road, neither can he carry them. The lay health worker persuades his fellows to walk the road to health, and provides the means of transportation, subsistence, and refreshment to those travellers who need them.

Laymen cannot build the road to health, neither can physicians advertise it and secure patrons for it. Both physicians and laymen

have a mutual need for each other, in designing and operating the road.

Concretely the leaders in the practice of public health are organizations of physicians, and organizations of laymen. A doctor treating only the sick who hire him will reach only a small proportion of the people of a community. An organization of doctors, working with an organization of the people, is necessary in order to reach all the people in a community. The civic duty to improve health rests equally upon the people and upon the medical profession.

The concrete representation of the people is the lay health organization,—usually the County Tuberculosis Committee. The concrete representative of the medical profession is the County Medical Society.

While the individual physician in the past has disclaimed a personal responsibility for the practice of public health, yet now he realizes that he himself is the medical profession. The fundamental act by which he may satisfy his conscience and practice public health is to support the leaders in his county medical society in their activities.

# MEDICAL PROGRESS

**Dangers of Intravenous Treatment**—John Howard Frick protests against the appalling degree to which intravenous injections are employed with anything but strictly aseptic conditions. Death has resulted in two instances after the accidental injection of 80 c.c. of air, and in four cases after the injection of between 125 and 150 c.c. of distilled water. If reactions such as pain and hemolysis of red corpuscles are to be prevented the solution must be neither too hot nor too cold. Other untoward effects of improper dosage or error in the technique have been obliteration of the vein, injection of the solution outside of the vein, which in the case of calcium chloride produces a most dreadful slough, and spasms and convulsions in a few instances. In giving an intravenous injection only the finest needle, a 16 gauge, should be used and the rule should be to take one minute for each 2 c.c. of the solution. If during an injection a patient complains of undue pain, or if there is unusual swelling at the site of the injection, the physician should desist. When a patient complains of backache during an injection it is a signal immediately to cease the introduction of the fluid. An increase in the pulse rate should likewise indicate cessation of injection. Most of the danger of intravenous medication does not lie with the administration as much as with the manufacture of the product. Few manufacturers have given sufficient consideration to the concentration coefficient. In many instances products deteriorate as the result of ageing, of reactions with glass, or of exposure to light or variations of temperature. Apparently the only way to overcome this difficulty is to make up a solution of a drug in bulk, allow it to age for six months or a year, assay and restandardize it and then seal it in alkali-free Jena glass. Only the so-called shoulder ampoule, that is easily broken without splintering the glass, should be used, in order to avoid the possibility of injecting fine particles of broken glass.—*Medical Journal and Record*, August 3, 1927, cxxvi, 3

**Nature of Allergens**—F. Klewitz and R. Wigand apply this term to substances which produce allergy and allergic diseases such as horse asthma and hay fever. They tested about 70 samples to determine basic qualities, employing them singly and in mixtures. Extracts of various crude substances, such as cattle hairs and meadow grass were made, and inoculation experiments were begun. The following were the conclusions at which they arrived: allergens are to a considerable extent heat-stable and can

stand boiling for some minutes at least. Coagulation takes place but the filtrate retains the allergic property and the active principle cannot be salted out by saturated cold ammonium sulphate solution. The allergens are fully dialyzable and pass through Congo-tight ultrafilters. Allergens are soluble in saline solution but not at all in alcohol, ether, chloroform and acetone. They contain no biuret substances and so of course do not give a biuret reaction. This is as far as we can determine the nature of these substances at present. Little is known of their molecular structure except that they are low molecularly and do not belong to the lipoids. They contain nitrogen, but to what extent they contain crude protein and protein split products is as yet unknown. While the activity of these allergens appears to depend on their nitrogen content we know of other allergic substances which do not contain this element. Allergens are probably not unit substances but mixtures.—*Klinische Wochenschrift*, July 23, 1927

**"Spontaneous" Cure of a Cancer of the Lip**—This case is reported by A. Avramovici of Bucharest. There could hardly be any doubt of the diagnosis of spinocellular epithelioma of the lower lip, for a biopsy was made by no less an authority than Professor Babes, and there could also be no doubt that the ulcerated mass healed completely and that the patient has been free from recurrence for four years. The patient, a man of 45, seems to have belonged to a cancer family, since his father and a brother are known to have succumbed to the disease. But there is some doubt as to the spontaneous character of the recovery because the patient went through two sharp attacks of malarial fever during the short interval between the first appearance of the precancerous wart and the disappearance of the lesion and the author himself seems to attribute the cure to this intercurrent experience. This would take the case out of the realm of spontaneous regression of the cancer. The patient took large doses of quinine during the febrile accesses and continued these after the disappearance of the fever, and quinine at one time was regarded as possessing anticancerous properties—notably by Jaboulay and his pupils. It might even be claimed that the biopsy excision gave a filip to recovery as partial operation for cancer has occasionally, though rarely, had this result. The patient had also been cauterized by the paquelin by his family doctor, and although this intervention seems to have aggravated greatly the course of the disease it may have

provoked a reaction in the connective tissue. The case ended dramatically, for the patient wished to go home before operation and when he returned 12 days later the lesion was nearly cicatrized, greatly to the astonishment of Professor Gerota, the surgeon. The only treatment in the interim had been hydrogen peroxide and rest—*Lyon Chirurgial*, May-June, 1927.

**Fasting Cures**—W. Arnoldi sums up a survey of this subject as follows: A diet poor in vitamins or lipoids, rich in salt, rich or poor in carbohydrate, protein, or fat, with unsuitable electrolyte content may cause serious damage. Dieting should be based on the study of the individual case to determine its actual requirement. We have learned how to diet a diabetic scientifically, but know much less about dieting in obesity, save when this is palpably the result of wrong diet. Apparently the patients best suited for diet suffer from anaphylactic, allergic, or angiospastic states in which presumably there are certain substances involved which act on the smooth muscle fibers of the bronchi, bloodvessels, etc. Here withdrawal of nutriment for a longer or shorter time may be of value. The author has seen good results from a fast of one to two weeks in appendicitis and gastric ulcer, followed then by a regulated diet. Fasting is known to lead to the elimination of uric acid and to complete catabolism. The same mechanism is seen in drug addictions, and fasting after withdrawal of the medicament (alcohol, morphine, quinine, nicotine, etc.) is of value in securing complete detoxication of the body. It is still undecided whether lues is amenable to fasting cures. For disburdening the economy of water and nitrogenous slag in chronic circulatory and metabolic affections short fasts of a day or so at a time are indicated, but they are contraindicated in tuberculosis, malignant diseases, and sepsis at least after cachexia has developed—*Deutsche medizinische Wochenschrift*, July 29, 1927.

**Acetonuric Vomiting in Children**—H. Seckel, writing in the *Munchener medizinische Wochenschrift*, July 22, 1927, says that there are three characteristic features of this affection, namely, vomiting, acidosis, and tendency to recur, to which we may add a fourth, the prompt response to the glucose treatment. The condition then is important rather because it may lead to diagnostic errors than for any serious significance in itself, for the severe emesis may suggest several very serious conditions such as ileus, meningitis, and appendicitis. In a case treated in 1926 occurring in a baby 19 months of age there had been incoercible vomiting for three days. The diet had consisted predominantly of carbohydrates with no meat or sausage and the attack had set in without prodromes. The phy-

sician who referred the case to the hospital had made the probable diagnosis of tuberculous meningitis. Examination showed nothing pointing to meningitis or appendicitis. The breath was strong of acetone and in the urine were found acetone and diacetic acid. The treatment consisted of rectal instillation of a 20 per cent solution of nutrient sugar which shortly did away with the evidences of acidosis, including the vomiting. Not all cases are so simple, however, for these patients sometimes come to laparotomy, the condition being imperfectly known to both pediatricists and surgeons. In the predisposed, acetonuric vomiting may be precipitated experimentally by an exclusive carbohydrate diet and these children usually are found in neuropathic families in which migraine, asthma, and other anaphylactic affections tend to appear. In theory insulin should be of value and may be tested in cases which do not respond promptly to glucose.

**Acute Infectious Multiple Sclerosis**—H. Pette of Professor Nonne's neurological clinic in the Hamburg-Eppendorf Hospital mentions the cases in this hospital during the past two years in which either encephalitic or myelitic symptoms were in evidence, the two at times being associated in the same patient. Two patients died out of a total of about twenty-five. Autopsy showed disseminated lesions of an acute type to which the term sclerosis could not yet be applied, and which were evidently of an infectious nature. Naturally with an affection of this nature involving both brain and cord a many-sided clinical picture resulted. The other cases which were purely clinical had not been under observation long but suggested an acute inflammatory stage of chronic multiple sclerosis, often with the probability of a series of exacerbations with intervals of quiescence. There is also the likelihood that some of these cases may recover entirely. We have the suggestion of an entire group of cerebrospinal affections which comprise lethargic encephalitis, acute poliomyelitis, and post-infectious encephalomyelitis (such as has recently followed vaccination in a few cases). In none of these affections has a living cause been demonstrated as yet, hence it is inferred that in the entire great group we have to do with an ultravisible virus. From this angle we may think of multiple sclerosis as the continuation or sequel of still another member of this group. It is of interest to note that multiple sclerosis has often followed cases of variola, measles, scarlet fever, whooping cough, and malaria, hence showing a marked analogy to post-infectious encephalomyelitis, an affection which has been too recently isolated to justify its autonomy—*Münchener medizinische Wochenschrift*, August 19, 1927.

may be suggested, as chronic appendicitis, colitis, peptic ulcer, various forms of calculus, functional dyspepsia, neurasthenia, etc. Thorough examination usually excludes organic disease of the cardiovascular system, liver, kidneys, spleen, etc. The chest, however, often presents some minor symptoms of an atypical character which are not tantamounted by radiology. In a few cases in which, as a result of erroneous diagnosis, laparotomy had been performed no anatomical lesions of any kind were found in the abdomen. Exploration of the abdomen by radiography likewise always proved negative. The treatment has never thrown any light on the nature of the phenomenon. If any hypothesis is possible it is probably that of a masked tuberculous, a tuberculous toxicosis. Apparently the disease attaches little importance to the von Pirquet test in these cases, although the test is positive. The patients are best treated, the literature suggests, as though they were subjects of latent or threatened tuberculosis. From the radiological angle this sign comes into comparison with the older abdominal tender spots.—*Lancet*, *Practica Medica*, July 4, 1927

**The Development of Cardio-Vascular-Renal Disease**—James P. O'Hare, writing in the *Boston Medical and Surgical Journal*, July 28, 1927 (vol. 4), presents a graphic scheme of the development of these conditions which leads to a better prognosis and more intelligent treatment of vascular disease. He shows that the hypertensive process which manifests itself at 35 to 45 years of age has its beginnings much earlier in life. He and Walker found that 76 per cent of their hypertensive cases had a definite family history of vascular disease, and 42 per cent of patients with high pressure gave a history that indicated vascular disturbance very early in life. This is tremendously important, because it indicates a possible prophylactic therapy in these vascular families. Hypertensive disease has, first, a non-hypertensive stage characterized by an abnormally responsive vasomotor system, manifested by symptoms such as nosebleed without apparent cause, high color, easy flushing, and clammy hands and feet. The second stage, which occasionally may be noted at about the age of 35, is characterized by a fluctuating systolic pressure, which gradually swings to higher levels. In this stage arteriosclerosis of the smaller blood vessels may possibly have its beginning. Certain it is that in the third stage, that of permanent hypertension, there is definite evidence of sclerosis in the smallest arteries and arterioles. Almost from the onset of the third stage, that of permanent hypertension, three factors may be observed, namely hypertension, retinal sclerosis, and cardiac hypertrophy. This last may be found by ordinary methods of diagnosis in over 80 per cent of all

hypertensive patients. Where such means do not readily disclose the hypertrophy, the seven-foot x-ray plate or the electrocardiogram almost invariably reveals it. From the point of cardiac hypertrophy, the course of the vascular disease may follow along any one of three lines or combination of these lines. The lesion may progress more in the cerebral vessels, producing cerebral arteriosclerosis and cerebral hemorrhage, or along the cardiac route, causing angina pectoris and congestive failure, or the kidney may be involved, leading to uremia or diabetes. Rarely does arterial disease confine itself to one system. With this mode of development in mind, it is important to remember that cerebral hemorrhage can occur in the "silent areas" of the brain without paralysis, and that in elderly persons with hypertension, edema, oliguria, albuminuria, and cylindruria, the chief difficulty with the heart may be

**Simmond's Disease (Hypophysary Cachexia)**—Professor N. A. Schereschewsky of Moscow refers to the description by Simmonds in 1914 of a new malady, termed by him hypophysary cachexia, characterized by precocious senility and a cachectic condition with apathy, somnolence, loss of memory, and other evidences of psychic involution. Frankel reported a second case in 1916 and Simmonds two additional cases in 1918. More recently other observers have been heard from and the conception of the disease, at first simple, has become complex, owing apparently to the participation of different segments of the hypophysis with the presence of various other hypophysary symptoms, and the further complication of basic processes which have originally involved the hypophysis, such as multiple sclerosis. The author quotes a case seen by Lichtwitz in 1922 which appears to have been the first to occur in a male, although the author had made no mention in his introductory remarks of any sex incidence. To this case he adds a personal one, likewise in a male. The condition could readily have been overlooked, for the patient was tuberculous with chronic myocarditis and achylia gastrica and his precocious senility would ordinarily have been set down to his chronic invalidism. The mechanism assumed for this case was a hemorrhage into the hypophysis which led to atrophy of the latter. Autopsy was procured with the following finds: the patient, a man of 28, appeared to be of age 42 to 45. There were numerous scattered hemorrhages in the base of the brain with atrophy of the anterior portion of the hypophysis, presumably due to hemorrhage, although there appears to have been no direct evidence to this effect. In conclusion it seems more appropriate to look on this condition of hypophysary presenility as a syndrome rather than an autonomous disease.—*Revue française d'Endocrinologie*, August, 1927

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York

## OUR SOCIETY—ITS DIVISION AND REUNION

In a previous editorial we have spoken somewhat of the founding of the Medical Society of the State of New York. The study of its early records should be of surpassing interest to every medical man. Much that we read in the accounts of its early transactions seems surprisingly modern.

Thus in the anniversary address delivered by Dr Nicholas Romaine on the second Tuesday of February, 1809, we read "Every community does honor to itself which treats with liberality men conspicuous in the learned professions for their genius and talents. It is only among an illiterate people that they become the subjects of jealousy and persecution. Where ignorance and prejudice abound there empiricism is maintained, and as the genial influence of science and human improvement prevail, quackery and every kind of imposition diminish." And one year later, President Romaine in his annual address again discussed that subject in these words "Though the evils of quackery seem so difficult prevented by Legislative power, yet it is always remedied by the influence of public opinion, which becomes more imposing, as the state of society is cultivated and improved. When Practitioners of Medicine are diligent and judicious in the exercise of their professions, they manifest to men of any discernment, their superior skill and success in the cure of diseases, and will show, in a striking point of view, the difference between the well educated Physician and Surgeon, and the mere pretender to professional knowledge."

And again in 1812, in his anniversary address, Dr Romaine declared "To patronize imposters is always disreputable to individuals and degrading to communities. Such a state of society as favors a degrading condition of any of the learned professions can only be changed by the slow operation of time, and may not be effected but by the succession of ages. In medicine especially, when people become attached to professional imposters, their pride and self love are excited to give support to such persons with more zeal than is ever experienced by regular physicians and surgeons. Those who contemplate to cherish the progress of medical science in this State must not imagine that the difficulties which long opposed the advancement of knowledge are even now entirely dissipated \* \* \* It is among the important duties of this Society to protect the profession from the intrusion of im-

proper characters and to secure the public from impositions."

It is apparent from these addresses delivered nearly a century and a quarter ago that the problem of the unlicensed practitioner, cultist and quack with which we of our time are so familiar, was well known in those early days.

Throughout the long history of our Society, there is constant evidence of its attempt to uphold and to protect the high standards of the medical profession and to do all within its power for the advancement of true science. We find, for example, that the establishment of the national pharmacopoeia was due to the influence of our Society. As early as 1818, the New York County Medical Society communicated with the New York State Medical Society suggesting the appointment of a committee to consider the formulation and adoption of a national pharmacopoeia. The matter was duly referred to a committee of the State Society, and one year later a complete pharmacopoeia was reported from our State Society to the district convention of the Middle States assembled at Philadelphia. The result of this was the national pharmacopoeia.

No more interesting or important chapter in our history can be found than that which relates to the founding of the American Medical Association. It should be a source of constant pride for us to remember that the founding of the A. M. A. was due to the Medical Society of the State of New York.

The first movement which was directed toward a convention of delegates drawn from all over the United States not only from the medical colleges, but from the regularly organized medical societies throughout the Union, was made at the annual session of our State Society held in February, 1839. A resolution looking to this end was proposed by Dr John McCall of Utica, the preamble of which recited that "WHEREAS, A National Medical Convention would advance, in the apprehension of this Society, the cause of the medical profession throughout our land, in thus affording an interchange of views and sentiments on the most interesting of all subjects—that involving men's health, and the means of securing or recovering the same," therefore it was resolved that a convention should be called for the following year in the City of Philadelphia. The physicians of the country at that time were apparently not ready for this new movement, and it was not until May, 1846, at the hall of the

Medical Department of the New York University, that the first convention of doctors from other States of the Union came together

One of the reasons which led to the call of the convention was the growing conviction among the physicians of that day that medical licensure should be in the hands of the state authorities. The movement, therefore, at first met with considerable opposition on the part of the medical schools. Indeed, so great was this opposition that at the very first session of the convention, a resolution was offered by one of the faculty of a medical school that the convention then adjourn *sine die*, but fortunately by an overwhelming vote, the resolution was not agreed to, and the following four resolutions were adopted

"First That it is expedient for the medical profession of the United States to institute a National Medical Association

"Second That it is desirable that a uniform and elevated standard of requirements for the degree M.D. should be adopted by all the medical schools in the United States

"Third That it is desirable that young men, before being received as students of medicine, should have acquired a suitable preliminary education.

"Fourth That it is expedient that the medical profession in the United States should be governed by the same code of Medical Ethics"

In the year 1846, therefore, the American Medical Association, due to the influence and the tireless efforts of our State Society, entered upon its long career of usefulness, and one year later, at the Hall of the Academy of Natural Sciences in Philadelphia, delegates from all over the United States attended. One of the resolutions then adopted carried into effect the purposes which had actuated the promoters of the American Medical Association in bringing the physicians from all sections of the Union into one harmonious body. From this resolution have come our present methods of state licensure

This resolution declared "*Resolved*, That the union of the business of teaching and licensing in the same hands is wrong in principle and liable to great abuse in practice. Instead of conferring the right to license on medical colleges and State and County medical societies, it should be restricted to one board in each State, composed in fair proportion of the representatives from its medical colleges and the profession at large, and the pay for whose services as examiners should in no degree depend on the number licensed by them"

As we pursue the narrative of the difficulties encountered by those farseeing men who foresaw the need and value of union, and who overcame all obstacles of prejudice and misunderstanding, and finally brought about the founding of the American Medical Association, we are reminded of the all but insurmountable task which con-

fronted those who, under the leadership of Washington and Hamilton, brought about the Union of the States, but as the work of Washington and Hamilton was to receive its final vindication in civil strife, so the work of the founders of the A. M. A. was to be interrupted by dissension

In 1883, thirty-seven years after the founding of the A. M. A., there occurred a rupture of relations between the national body and our State Society, which was not to heal for nearly a quarter of a century. It was at an annual meeting of the State Society in the year 1883 that a resolution was offered intended to take the place of a formal code of ethics which had been adopted the year before. The resolution was called the "no code" resolution. The result of this was that the New York State Medical Society severed its affiliation with the national body. But those who dissented from the principle of that resolution and who desired to continue the affiliation with the A. M. A., in 1884 organized the New York State Medical Association. These two rival State organizations continued to exist side by side for twenty-one years, and in each county there was a county association as well as a county society.

This was an exceedingly unfortunate division—as unfortunate a division as would have been the continued separation of the North and the South. As time went on, however, what was apparent to so many on the occasion of the unfortunate differences of opinion, became obvious to increasing numbers of the profession, namely, that in union there is strength, and in disunion, frustration. As the nineteenth century dragged on to its close, a new generation of medical men was coming into practice, who were unfamiliar with and therefore entirely untouched by the dissension which had led to the unfortunate division of the medical profession. The influence of these new men and the wise counsel of the older heads who had deplored the original dissension, led finally to a consideration of measures designed to heal the old wounds.

Speaking of the conditions which obtained while the division lasted, Dr. John Wyeth, from whose interesting autobiography we have quoted in a previous editorial, declared "The two hostile camps created an unfortunate situation. The regular medical profession, in its warfare against quackery and ignorance and malpractice, needed to be a solid body with a united front. For twenty years in the Empire State it was as a divided house, and, although it did not fall, it was leaning over so far that the enemies of progress in medical affairs smiled in their sleeves at the tottering structure. The only redeeming feature of this deplorable situation was that the doctors at variance were acting from conviction and had no axes to grind. It was the old, old story of the shield with its two sides, and the difficulty was to induce the tilting knights of the spatula and scalpel to study carefully the other side

There was not a time in all this unhappy controversy over questions of ethics when a compromise could not have been effected. The code of ethics was a sort of medical family Bible, setting forth some very strict rules of conduct, all of which even those who stood out for them didn't always follow. There was a middle and a safe way, and it fell to my lot to be of service in finding the path which led to a united profession."

During the fall of 1900, when the New York State Medical Association was holding its annual meeting in New York City, Dr E. Eliot Harris, prominent even then in its affairs, called on Dr Wyeth with a proffer for the nomination for the presidency. Dr Wyeth saw the opportunity to attempt to reunite the profession in the State, and told Dr Harris that he would accept the office if he could be assured by those influential in the organization that they would assist in bringing about a compromise with the old New York State Medical Society, from which would result a reunion with the members of both bodies in the national association. The assurance was given, and Dr Wyeth was elected president of the New York State Medical Association.

What took place is told by Dr Wyeth in these words: "Relying upon the integrity, loyalty, and the extraordinary ability of Dr Harris, I met him several times, and we finally formulated a plan which we proceeded to carry out. Our first move was the inauguration of an active campaign for increasing the membership of the association, and in doing this we organized new bodies in counties where none had existed. Meetings were held all over the State, attractive papers were read by our most eminent men, and a great many new members were obtained. In two counties we won over to the association the regular society organizations. When the movement was at its height I called on the leaders of the society and found them ready to listen to our overtures. While this was pending the profession throughout the United States, having learned of what was being attempted in the Empire State, showed their approval by electing me President of the American Medical Association at the St. Paul meeting in June, 1901, and at the request of the New York delegation the next annual meeting of the national organization was held at Saratoga in 1902. To this meeting all the members of the society were invited, and the work of fraternization went bravely on. Among the prominent physicians of the State who lent invaluable aid at this juncture was my friend and former partner in the college quiz, Professor Joseph D. Bryant. In order finally to complete the fusion certain legal steps became necessary. Dr Bryant, already prominent in public as well as professional affairs, took charge and with his usual tact and skill carried the reunion to a successful conclusion."

The legal steps necessary to bring about the

consolidation were troublesome and complicated in their nature, and were not effected without the aid of legislation. In 1904, a law was passed authorizing "the consolidation of the Medical Society of the State of New York and the New York State Medical Association." A long and somewhat complicated agreement was thereafter and on the 19th day of October, 1905, entered into between the Medical Society of the State of New York by Joseph D. Bryant, president, and the New York Medical Association by Allen A. Jones, which provided for the terms of the consolidation. Two months later, on the 9th day of December, 1905, the records of the Supreme Court reveal that at a Special Term of the Supreme Court, held in the City of Rochester, an order was duly entered whereby the two societies were consolidated on the terms and conditions of the agreement previously entered into. The old name of the Medical Society of the State of New York was preserved, and the members of the joint committee of conference appointed to bring about the consolidation were made ad interim the officers of the new consolidated society.

The medical profession should never forget the services performed by these men, who were Dr Henry L. Elsner, Dr A. Jacobi, Dr A. Vander Veer, Dr George Ryerson Fowler, Dr Frank Van Fleet, Dr E. Eliot Harris, Dr Julius C. Bierwirth, Dr Alexander Lambert, Dr Parker Syms and Dr Wisner R. Townsend.

Thus, at last, the breach which had separated the profession for a quarter of a century was healed. The healing had taken place in 1906 in time for the celebration of the 100th anniversary of the founding of the Medical Society of the State of New York. After a quarter of a century of unfortunate division, reunion had been effected. All the differences were healed, all the misunderstandings adjusted, and the Medical Society of the State of New York, the founder and the originator of the A. M. A., entered upon its second century of useful life.

Twenty-one years of this second century have already passed. We find the Society stronger, more effective, more cohesive, more determined to uphold the high standards of the profession, more resolute to assist in the exposure and elimination of quacks and charlatans, and more appreciative of the benefits of friendly intercourse and the advantages to be derived from united action than ever before in its history.

The writer well appreciates that many of those who were responsible for the healing of the wounds are now living, and whose knowledge of these transactions vastly transcends all that he may have gleaned from the records. To the new generation of doctors, however, that has come into practice in the past twenty-one years, the writer has felt that this brief excursion into our history might be not without interest.

## X-RAY FILMS—PARTIAL ALOPECIA

The patient was under the care of a physician who had advised him to procure X-ray pictures to assist such physician in the diagnosis and treatment of the patient's condition. The patient went to the defendant, a roentgenologist, for the purpose of having the X-rays of his head and face taken. X-rays were taken, but were not sufficiently clear and did not satisfactorily show the patient's condition. A second set of X-rays were then taken.

It is charged that the roentgenologist in the taking of the pictures did not use proper care and skill but experimented with the patient, and that by reason of the experiment of the roentgenologist, the patient's head and scalp were injured and his hair was caused to fall from his head, leaving bald spots at various places upon the head. That prior to the taking of the X-rays the patient had had a good crop of hair and that since the films were taken the plaintiff claims to have been compelled to seek medical aid in an endeavor to relieve the injury to his scalp and the roots of his hair. By his action he sought to recover damages against the defendant roentgenologist.

The plaintiff was referred to the roentgenologist for the purpose of having X-rays taken of the frontal sinus and antrum. At the first session three pictures were taken of the

head, the first of the left cheek, with a skin target distance of 25 inches, spark gap  $4\frac{1}{2}$  inches, 32 milliamperes and 10 seconds exposure. Films were also taken of the right cheek with the same factors of dosage. These films being unclear and indefinite four days later another set of films were taken of the right cheek and left cheek, the factors being skin target distance 25 inches, spark gap  $4\frac{1}{2}$  inches, 32 milliamperes and 15 seconds exposure. About five or six days after the last films were taken the physician who was attending the plaintiff for his sinus condition noticed that the hair was falling out at the back of the patient's head. There was no redness there to indicate that the patient had suffered any X-ray reaction. When he was again seen about a month later this physician observed a large bald spot on the back of the plaintiff's head, the spot being about three inches in diameter. Several months later when the plaintiff was again seen by this physician it was observed that the hair was growing in again and the physician believed that within a short time the plaintiff would again have a full head of hair just as he had before the X-ray films were taken.

When this action reached its place upon the calendar for trial the plaintiff failing to prosecute, the complaint was dismissed.

---

## NON-PAYMENT OF BILL—MALPRACTICE COUNTERCLAIM

During the protracted illness of a patient, a physician had rendered services as an expert diagnostician and gastro-enterologist. His services extended over a period of several months and consisted of a number of visits to the patient's home and also of the patient's visits to the physician's office. During the period of treatment the patient paid part of the physician's bill and when the services were completed and after much dunning by the physician, another installment of the bill was paid. The balance of the bill remained unpaid and the physician then sought to collect the same through an action. To the physician's claim the patient interposed a counterclaim of alleged malpractice charging the defendant generally with negligence and carelessness in his examination and treatment and also claiming that the charges made for services by the physician were excessive, which amounts he demanded be refunded to him. The patient claimed damages in that he was put to additional expense for further hospital and medical treatment and was prevented from attending to his usual business.

This patient had been suffering from a stomach ailment for some period of time and upon the advice of his brother, a physician, was referred to the plaintiff in this action for expert advice. After a thorough examination the plaintiff diagnosed the condition as a duodenal ulcer and had the defendant go to a private hospital, where he remained for about a month under treatment by the plaintiff. After leaving the hospital the patient called on the plaintiff physician several times at his office. During the course of the treatment X-ray pictures were taken of the patient's stomach. This physician's treatment was proper and correct in all respects, and the bill rendered for the services was reasonable. The refusal of the patient to pay and the interposition of a counterclaim of alleged malpractice was one of the numerous attempts of ungrateful patients to avoid payment of a just bill of a physician.

The malpractice counterclaim was withdrawn and the unpaid balance adjusted between the parties.

# NEWS NOTES

## THE EIGHTH DISTRICT BRANCH

One hundred and twenty physicians, sixteen of whom were women, gathered in the Community House at Warsaw, Wyoming County, at 10 30 A M., October 6th, for the twenty-second Annual meeting of the Eighth District Branch, with the President, Dr George W Cottis, in the Chair (The Eighth District Branch began its meetings in the fall of 1906, the first year of the reorganized State Medical Society. The other District Branches began their meetings in 1907 and so the number of their meetings is one less than that of the Eighth District Editorial note)

Dr James E Sadlier, President of the Medical Society of the State of New York, in his official address, spoke of the vital problems now before the parent organization, and of the duties and responsibilities of every county and district branch society to help in their solution. He emphasized the fact that the public is demonstrating a keen appreciation of the progress of organized medicine by supplying funds for the erection and maintenance of hospitals and the multiplication of clinics.

Dr John A Card, Vice-Speaker of the House of Delegates of the State Medical Society, assured the members that their officers had no thought of increasing the individual assessment as a result of the increased activities of the Society. He said the Trustees of the Society carefully guard against extravagance in the expenditure of funds. He spoke of the task of re-writing the by-laws, and said the committee in charge of the work will appreciate constructive suggestions from members. He asked members to send news items to Dr Orrin S Wightman, editor-in-chief of the State Journal. Dr Wightman, he said, is anxious to improve the service for gathering news of interest to the medical profession of the entire State.

Dr Card remarked that in the annual registration of physicians with the State Department of Education, more than 2000 doctors had made themselves liable to a penalty by failure to register in 1926. He brought out the fact that the Committee on Grievances, created by the recent amendment to the Public Health Law, is not a committee of the Society, but its members are appointed by the Regents, and the State Society acts only in an advisory capacity.

Dr Edgar W Phillips of Rochester gave an address on "Surgical Aids in the Treatment of

Pulmonary Tuberculosis", and the paper was illustrated with lantern slides.

Dr C Ward Crampton of New York gave a paper on "The Proper Examination of Apparently Healthy Persons", accompanied by a demonstration of the diagnostic procedure on a living subject. He explained the difference between a health examination and a disease examination, and stated that the physician's office is the place for an ideal examination. He said that by means of these examinations the average span of life has been extended from 35 years to 58 years, and that disease can be discovered long before the patient becomes a patient. He declared that health examinations are not successful when fostered and pulled along by some charitable organization. The examination is successful, he said, when the physician is adequately paid for such service, and asserted that health examinations increase the demand for minor repair work by specialists. He said that of 2000 examinations made at the New York Post-Graduate Medical School and Hospital, 1200 references of cases had been made to physicians. He cautioned doctors not to halt the examination when they heard a heart murmur or discovered a fibrous condition of the lungs, but to go through with the entire routine and send the individual on his way in a happy frame of mind, and yet convinced that he needs medical attention when conditions warrant treatment. He described pre-clinical signs as age-producing signs caused by toxin-producing conditions, and called attention to the difference in blood pressure while the patient is in a standing position and while he is in a lying posture.

Dr Robert H Halsey of New York, spoke on "Some New Problems in Heart Disease", which, he said, were really new aspects of old problems. He stated that the death rate from heart disease in New York State, according to population, is the second highest in the United States. Rheumatic infection constitutes over 55% of mortality from heart disease, and it is a relatively fatal disease for persons between the ages of 15 and 25 years. Most rheumatics die before the age of forty. Dr Halsey dwelt at length on the etiological factors of heart disease. Rheumatic infection, he said, includes rheumatic fever, acute tonsillitis, chorea, and streptococcus infection. He urged physicians to recognize the source of infections which do damage to the heart and to put it down on the death certificate. Get autopsies whenever pos-

sible and make known the etiological factors. Such reports will aid the committee of the State Society engaged in a study of etiology of heart disease.

Dr Halsey's talk was discussed by Dr Nelson G Russell and Dr Thomas J Walsh of Buffalo.

Dr Thomas P Farmer, Chairman of the Committee on Public Health and Medical Education, of the State Society, gave a short address on the relation of the general medical practitioner to public health activities. He urged every county medical society to appoint a public health committee which shall dominate health work in the county,—not boss, but lead, he said. Dr Farmer emphasized the importance of publicity as a means of promoting post-graduate work conducted under the auspices of the county medical society.

Dr George J Eckel, President of the Buffalo Academy of Medicine, invited members of the Society in counties adjacent to Erie to become non-resident fellows of the Buffalo Academy of Medicine. He pointed out the advantages of closer cooperation between county medical societies and an institution devoted chiefly to scientific medicine.

The following officers were elected for two years beginning at the close of the annual meeting of the State Medical Society: President, Dr Thomas J Walsh, Buffalo, First Vice-President, Dr W Ross Thomson, Warsaw, Second Vice-President, Dr Raymond B

Morris, Olean, Secretary, Dr W Warren Britt, Tonawanda, Assistant Secretary, Dr Russell H Wilcox, Tonawanda, Treasurer, Dr Fitch H Van Orsdale, Belmont.

At the close of the meeting of the District Branch, Dr Harry R Trick, President-elect of the State Medical Society, delivered the dedicatory address of the George E Skiff Memorial Laboratory, and said in part "Dr Skiff died, aged 31, on August 9, 1925, as a result of an infection contracted in his line of duty. He graduated in Medicine in 1920 from the University of Buffalo, and came to the Warsaw Hospital in the following year. He was entrusted with responsibilities beyond his years. Not infrequently he carried on the entire surgical work of the hospital. He was also entrusted with the establishment and equipment of a laboratory which should do clinical work for the hospital, and public health work for Wyoming County. His work was scarcely finished ere his end came. The reaction of the entire community to this tragic loss was the erection of a laboratory wing as a symbol of his high ideals and his devotion to duty."

"To inherit ideals is a divine birthright,  
To acquire ideals is a supreme achievement,  
To inspire ideals is to give life,  
To vitalize ideals is a great duty,  
To bequeath ideals is a magnificent legacy."

"To Dr Skiff, whose life exemplified these ideals, we dedicate this memorial laboratory."

#### FOURTH DISTRICT BRANCH MEETING

The twenty-first annual meeting of the Fourth District Branch of the Medical Society of the State of New York was held on Tuesday and Wednesday, October 11 and 12, 1927 in Schenectady. The two-day session was planned so as to accommodate those who come from a distance. Since the District comprises almost the entire northeastern section of the State, including the Adirondack region, the physicians from the northern counties would have to spend half a day to reach the meeting place and would have to stay all night. By holding the sessions on Tuesday afternoon and evening and Wednesday morning, they could attend them and still devote only two days to them.

The sessions on Tuesday afternoon were held in the Ellis Hospital. The program consisted of clinics as follows:

2 P M—Pathological Demonstration

a "A Family of Bleeders"

b "Relation of the Spleen to Purpura Hemorrhagica"

2 45 P M—Pediatric Clinic

James J York, M D

Frank vander Bogert, M D

Alton Goldbloom, M D, Montreal (by invitation)

3 30 P M—"Fracture Cases"

Charles McMullen, M D

Charles Woodall, M D

Philip D Wilson, M D, Boston (by invitation)

The evening meeting was held in the Mohawk Golf Club and was begun with a social dinner given by the Schenectady County Medical Society.

Dr James E Sadler, President of the Medical Society of the State of New York, gave an address on the service which the State Society can render the physicians of New York State. He referred to the ideals stated in Article I of the Constitution of the State Society, in which one great purpose was the education of the physicians, and another the enlightenment and direction of public opinion in regard to the problems of medicine. Physicians have always stood for education of their own number, but it is only in recent years that methods have been

developed for the education of the public. The great problem before the Medical Societies today is that of leadership in the work of directing the public opinion—a work which physicians have permitted lay organizations to do. It is a fact that lay organizations are better equipped to carry on this work than physicians, but it is also a fact that physicians should direct the work and set the standards of that education.

The State Medical Society, through its committee on Public Relations, is rapidly developing a standardization of the fields of work of the medical societies and of the lay organizations, and the two bodies will ultimately solve the problem of how to educate the public in medical matters.

Dr Daniel S. Dougherty, Secretary of the Medical Society of the State of New York, spoke on the work of the Secretary's office. While the President and the Committees of the State Society were dealing with general principles and policies, the Secretary dealt largely with details brought up by individual doctors. Questions flowed into his office daily asking about such matters as how to register with the Board of Regents, when a meeting was to be held, how to secure a speaker for a meeting, and how to secure malpractice defense. Doctors are only mildly interested in the standardization of methods of public health work and the procedure of county societies until something occurs in which they are vitally interested, and then they seek help from the Secretary's office and it is always given. A staff of five persons is employed in the Secretary's office to keep the records of membership and to conduct the immense amount of business required in dealing with the individual doctors. It is the policy of the State Medical Society to give service to every member that asks for it, and the records on which the information is based is on file in the central office. Few members realize the immense amount of detailed work that is neces-

sary in order that information regarding the individual members of the county societies may be instantly available when it is needed. This is the kind of service which appeals to the individual members and makes them feel that the State Society is in friendly touch with every doctor in the State.

The principal feature of the evening was a demonstration of "Making Sound Visible and Light Audible," by Mr. John B. Taylor, consulting engineer of the General Electric Company. Mr. Taylor showed lantern slide pictures of sound waves, and then gave a demonstration of the production of a record of a wavy line of light shooting back and forth on the screen as an illuminated mirror was actuated by sound waves.

Mr. Taylor also showed the record of the sound waves of an orchestra impressed on a moving picture film, and then reproduced the music of the orchestra as a beam of light passing through the film actuated a photo-electric cell which actuated a sound reproducer similar to that of a radio receiver.

The program of Wednesday morning was as follows:

- 9 30 A M—"The Importance of the Work of the Committee on Medical Education and Public Health to the Medical Profession" Thomas P. Farmer, M D, Syracuse  
 "The Costal Excursion in Health and Disease," Henry A. Bray, M D, Ray Brook Sanitarium  
 "Physicians and Intelligence Test" Ira S. Wile, M D, New York City  
 "Acute Intestinal Obstruction with Report of Cases" Lew H. Finch, M D, Amsterdam  
 "A Study of the Prognosis in Cancer of the Breast" Edwin MacD. Stanton, M D, Schenectady

#### FIFTH DISTRICT BRANCH

The twenty-first annual meeting of the Fifth District Branch of the Medical Society of the State of New York was one of the most interesting and inspiring that has ever been held.

The registered attendance was 253, including 45 medical students from the University of Syracuse, the senior class being excused from college in order that it might attend the scientific sessions. One student said that the meeting was a revelation to him, that he had no idea of the extent to which the medical education of doctors was carried after their graduation. The meeting was also an inspiration to

him as it showed a spirit of comradeship among the physicians like that among the medical students at college. He suggested that a few lectures on the work of a County Medical Society would be of great benefit to the students in showing their relations to one another after they begin practice.

The scientific session consisted of two remarkable addresses. Dr. Temple Fay of Philadelphia, gave a lecture with lantern slides on "Operable Lesions of the Brain and Spinal Cord" in which he showed some of the nervous conditions which are now diagnosed and treat-

ed by operation, especially those lesions produced by carcinoma and other tumors

Dr John Osborn Polak of Brooklyn, gave an outline lecture with lantern slides, on "The Present Day Trend in Obstetrics and Gynecology" His lecture was an index of the conditions with which all physicians should be familiar, rather than a detailed description of any one particular lesion

Dr James E Sadler, President of the Medical Society of the State of New York, described the policy of the State Medical Society in assisting the county societies in order to bring all up to the standard of the best If one Society does an excellent piece of work, then all other societies should know of it and be urged to imitate it The function of medical societies in educating physicians had been largely assumed by academies of medicine in the larger cities, and so there had sprung up one group composed of scientific leaders, and another group composed of physicians with less skill and learning along special lines—the family doctors The tendency now is that the academies of medicine and the county medical societies should come together more closely, either by actual union or by the academies assuming the scientific education of the county societies, and the county societies taking over the practice of public health and civic medicine The State Medical Society is assisting physicians in their programs for all lines of work

Dr Daniel S Dougherty, Secretary of the Medical Society of the State of New York, told of the work the Society is doing He said that much of the activity of his office consists in assisting county medical societies in the discussion

of practical plans for their work The State Society is engaged in a concrete *art* of the practice of organized medicine, rather than the philosophical discussion of the *science* of medicine The State Society must produce tangible results from all its activities and avoid contention over debatable subjects

The New York State Journal of Medicine contains a summary of things actually done by the State Society, rather than a rapid record made up of details which have only a local interest, and which are repeated over and over again as the same problems come up in different societies

Dr Thomas P Farmer, Chairman of the Committee on Public Health and Medical Education, described the work of his committee, and urged those societies who wish to have assistance from the State Society to make their applications early, for most of the funds and available speakers were already allocated in accordance with the demands which have been made upon this committee

The program of the evening session was as follows

"The Development of Rheumatic Heart Disease," Samuel A Levine, M D, Boston, Mass Discussion opened by I Harris Levy, M D, Syracuse

"Physiotherapy in the After-Care of Industrial Accidents," Harry E Stewart, M D, New Haven, Conn Discussion opened by Charles P Hutchins, M D, Syracuse

"The Health Examination—Scientific and Practical Aspects," C Ward Crampton, M D, New York City Discussion opened by Clifford R Hervey, M D, Oswego

---

## THE PROGRAM OF THE SECOND DISTRICT BRANCH

The Committee on Arrangements for the meeting of the Second District Branch has issued the following program, which is unique in both form and content

The Second District Branch of the Medical Society of the State of New York is composed of Kings, Queens, Nassau and Suffolk Counties—ALL of Long Island, as any student of geography knows

On November 9th, 1927 (mark it in your memory or ON your engagement pad) the doctors of medicine in these counties will meet at the Brooklyn Chamber of Commerce, Court and Livingston Sts, at a Dinner at 6 30 p m, and a Meeting at 8 30 p m The price of the Dinner \$3 The Meeting costs Nothing

At the Dinner many of the good fellows of the profession on Long Island will make merry with jest and story around the festive board

There will be no speeches—the eats will tickle the gastric mucosa of the most fastidious epicurian

There will be no sad, out-of-tune orchestra or pink-cheeked tenors warbling off key

Just food—good fellows—laughter—shop talk—the latest funny story and merry quip—and all for the modest three simoleons

For years the District Branch meetings have been held at 1313 Bedford avenue, in the Library Building of the Medical Society in the County of Kings—MacNaughton Auditorium All right as far as it went—fine medical atmosphere and all that, but at least two of the County Societies find themselves en route to the meeting at meal-time or starting toward Brooklyn before dinner, or finding it too late if they start after dinner at home The President of the Branch wants to see all alibis for non-attendance removed, and to that end has

developed for the education of the public. The great problem before the Medical Societies today is that of leadership in the work of directing the public opinion—a work which physicians have permitted lay organizations to do. It is a fact that lay organizations are better equipped to carry on this work than physicians, but it is also a fact that physicians should direct the work and set the standards of that education.

The State Medical Society, through its committee on Public Relations, is rapidly developing a standardization of the fields of work of the medical societies and of the lay organizations, and the two bodies will ultimately solve the problem of how to educate the public in medical matters.

Dr Daniel S. Dougherty, Secretary of the Medical Society of the State of New York, spoke on the work of the Secretary's office. While the President and the Committees of the State Society were dealing with general principles and policies, the Secretary dealt largely with details brought up by individual doctors. Questions flowed into his office daily asking about such matters as how to register with the Board of Regents, when a meeting was to be held, how to secure a speaker for a meeting, and how to secure malpractice defense. Doctors are only mildly interested in the standardization of methods of public health work and the procedure of county societies until something occurs in which they are vitally interested, and then they seek help from the Secretary's office and it is always given. A staff of five persons is employed in the Secretary's office to keep the records of membership and to conduct the immense amount of business required in dealing with the individual doctors. It is the policy of the State Medical Society to give service to every member that asks for it, and the records on which the information is based is on file in the central office. Few members realize the immense amount of detailed work that is neces-

sary in order that information regarding the individual members of the county societies may be instantly available when it is needed. This is the kind of service which appeals to the individual members and makes them feel that the State Society is in friendly touch with every doctor in the State.

The principal feature of the evening was a demonstration of "Making Sound Visible and Light Audible," by Mr. John B. Taylor, consulting engineer of the General Electric Company. Mr. Taylor showed lantern slide pictures of sound waves, and then gave a demonstration of the production of a record of a wavy line of light shooting back and forth on the screen as an illuminated mirror was actuated by sound waves.

Mr. Taylor also showed the record of the sound waves of an orchestra impressed on a moving picture film, and then reproduced the music of the orchestra as a beam of light passing through the film actuated a photo-electric cell which actuated a sound reproducer similar to that of a radio receiver.

The program of Wednesday morning was as follows:

 "Acute Intestinal Obstruction with Report of Cases" Lew H. Finch, M D, Amsterdam  
 "A Study of the Prognosis in Cancer of the Breast" Edwin MacD. Stanton M D, Schenectady

## FIFTH DISTRICT BRANCH

The twenty-first annual meeting of the Fifth District Branch of the Medical Society of the State of New York was one of the most interesting and inspiring that has ever been held.

The registered attendance was 253, including 45 medical students from the University of Syracuse, the senior class being excused from college in order that it might attend the scientific sessions. One student said that the meeting was a revelation to him, that he had no idea of the extent to which the medical education of doctors was carried after their graduation. The meeting was also an inspiration to

him as it showed a spirit of comradeship among the physicians like that among the medical students at college. He suggested that a few lectures on the work of a County Medical Society would be of great benefit to the students in showing their relations to one another after they begin practice.

The scientific session consisted of two remarkable addresses. Dr. Temple Fay of Philadelphia, gave a lecture with lantern slides on "Operable Lesions of the Brain and Spinal Cord" in which he showed some of the nervous conditions which are now diagnosed and treat-

posed of those in which criminal work is done, principally abortions

The better class of private hospitals welcome inspections of both their equipment and their methods. Their histories are well kept and are open to inspection, and all their affairs are conducted in a frank, open manner. This cannot be said of many private hospitals and nursing homes.

There is a great temptation for the operators of private hospitals to ignore histories either from simple carelessness or intentional design, but patients do not know the high standards which the medical profession expects every doctor to maintain, especially a doctor who has sufficient prestige to operate a private hospital. Inspection by an official body is necessary in order to control the private as well as the public hospitals. A definition of what hospitals are is necessary in order to frame a law regulating them. In general a hospital should be defined as any building in which two or more sick persons are intentionally placed for diagnosis or treatment.

A law regulating private hospitals was proposed for New Jersey last year but was not introduced into the Legislature. However, a law regulating the nursing homes was introduced and was passed during the closing hours of the Legislature after physicians had been assured that it would not be enacted. While the law was a step in the right direction, it was futile in that it carried no penalty for violation.

The law provided that the Commissioner of Institutions and Agencies should prepare a blank form for recording the data of every nursing home as a basis for licensing it. Commissioner Ellis had prepared an excellent form which was unusually complete and practical. It required information regarding the buildings and grounds, the equipment for giving both personal and professional care, the medical service, with names of both doctors and nurses and the time spent in the care of patient, laboratory facilities, case records, and so on through a long detailed list of inspection items. Its defect is that it does not evaluate the personal skill and character of the physicians.

Dr Sadlier said that he had secured information from nearly every state regarding the control of hospitals and had found that very little control was exercised over the private hospitals. The inspections by the American College of Surgeons had been the principal factor in raising the standard of public hospitals and the larger private ones. But forty-seven per cent of patients in the United States are in hospitals of less than fifty beds and these are not inspected or subjected to control.

Dr Sadlier said he was heartily in favor of the establishment of an official system for the

inspection and licensing of all hospitals and nursing homes.

Dr Morgan favored the control of the hospitals by an official body. The American College of Surgeons was a select body whose members possessed unusual attainments and usually practiced in large hospitals. But most private hospitals were small and were conducted in communities where surgeons of unusual eminence were not available. Yet every community could produce men of ability and character who could conduct the hospital and perform operations according to high professional standards.

Dr Hammond said that it would not be proper to assume that all private hospitals fail to conform to the highest standards of the profession. He knew private hospitals in which the owners follow the best methods and require all doctors who are associated with them to apply the same high standards. Poor histories was a common defect in the private hospitals, for their managers often seemed to think that the absence of control relieved them from the obligation of making records. One item of official control should be the requirement to keep complete records of all cases. The American College of Surgeons had been the means of educating the doctors of approved hospitals to write histories, and official control of the private hospitals would also produce histories of real value.

The conference unanimously adopted a proposition that the President of each State Society should appoint a representative to serve on a committee of three which should devise a plan for the regulation of private hospitals and should prepare a bill to be submitted to the Legislatures of the three States.

It was decided to hold the next conference in New York City some time during February. The suggestion was made that the topic for discussion be "Expert Medical Testimony".

While the formal transactions of the Convention well justify the holding of the meeting, yet the information gained in informal conversations were also of very great value.

Dr Morgan stated in an informal conversation that the visiting of county societies had been one of his pleasurable duties as president. He had visited one society which had only fourteen members and his was the first visit that a State Officer had ever made to that Society. (See page 1222)

Dr Morgan also said that the system of public health administration of the State Department of Health provided for a county health officer for every county, paid by the State. These health officers were doing an excellent work in coordinating the public health work of the doctors with that of the State. He also said that in his course of lectures on

provided a program for a meeting preceded by a dinner that cannot be missed in these days of economic pressure, public relations and what-not in the medical field

At 8 30—four speakers—each an artist in his own field—will tell how the four County Societies have been doing good and great things for years. Hospital studies, tuberculosis prevention, cost of medical care and its relation to dispensary procedures, comparison of public and private control of syphilis, graduate medical education, development of county health work, and many other activities, are under way, completed, or beginning. In which county, and in what degree? That will be told in four short thumbnail sketches by

Ross of Suffolk,  
Van Kleeck of Nassau,  
Riley of Queens,  
Welton of Kings

Next Dr James E Sadlier, President of the Medical Society of the State of New York, will tell us about the relations of the State Medical Society to the physicians of Long Island

And now you are going to hear something! Something to open your eyes and make you

sit bolt upright in your chairs. What has gone before will be an introduction to the subject of the evening—a speaker of voice, of physique, of patriotism for his County and State, and of loyalty to his profession. With the background of reminder information of what is being done, and has been done by the constituent societies of our Branch, we will the better appreciate the situation in Cattaraugus County, as delineated by

Joseph P Garen, M D, President of the Medical Society of the County of Cattaraugus

The Brooklyn Chamber of Commerce is interested in health work, has a public health committee under the chairmanship of one of our Kings County physicians, and is a participant in the Brooklyn Health Council with the Medical Society of the County of Kings

The Long Island Chamber of Commerce is considering, with the cooperation of the medical profession, the formation of a public health committee

The Dinner and the Meeting will be held in the new home of the Brooklyn Chamber of Commerce

Will you be there on November ninth?

### TRI-STATE CONFERENCE

The Seventh Tri-State Conference of the officers of the Medical Societies of New York, New Jersey and Pennsylvania was held on October 22 in the Hotel Seabright, Atlantic City, with Dr Walt P Conaway of Atlantic City, President of the Medical Society of New Jersey, presiding. Others present were—from New Jersey, Dr J B Morrison, Secretary of the Medical Society of New Jersey, Dr E R Mulford, First Vice-President, Dr Henry O Reik, Editor of the Journal, from Pennsylvania, Dr A C Morgan, President of the State Society, Dr William Truman Sharpless, West Chester, President of the Board of Trustees of the State Society, Dr Frank C Hammond, Editor of the State Journal, and from New York, Dr James E Sadlier, President of the State Society, Dr J S Lawrence, Executive Officer, and Dr Frank Overton, Executive Editor of the State Journal

The program consisted of a discussion of State Control of Private Hospitals, which was led by Dr J B Morrison. The speaker said that a private hospital was one that did not receive public funds of any kind, either as public appropriations or as contributions, but was owned and supported by a person, or partnership, or corporation, as a business enterprise. He referred especially to hospitals which doctors establish for their own cases,

and to nursing homes conducted by nurses. These hospitals are not subject to inspection or control by any official agency while, on the other hand, community hospitals are licensed and inspected by an official body of the State,—in New York by the State Board of Charities, in New Jersey by the Department of Institutions and Agencies, and in Pennsylvania by the Department of Welfare

The American College of Surgeons is an unofficial agency that inspects hospitals and gives them ratings, but it deals with very few private hospitals in the Eastern States

Dr Morrison divided private hospitals into four classes

1 Those conducted by competent physicians who measure up to the standards of the American College of Surgeons, and the College of Physicians

2 Those conducted by men of character and ability who are not recognized by the American College of Surgery or Medicine

3 Those conducted by physicians for the reception of their own cases. Many of these physicians are extremely individualistic, and do not mingle with their medical brethren, and no one knows the kind of treatment that they give. Nursing homes may come in this class

4 A fourth class of private hospitals is com-

posed of those in which criminal work is done, principally abortions

The better class of private hospitals welcome inspections of both their equipment and their methods. Their histories are well kept and are open to inspection, and all their affairs are conducted in a frank, open manner. This cannot be said of many private hospitals and nursing homes.

There is a great temptation for the operators of private hospitals to ignore histories either from simple carelessness or intentional design, but patients do not know the high standards which the medical profession expects every doctor to maintain, especially a doctor who has sufficient prestige to operate a private hospital. Inspection by an official body is necessary in order to control the private as well as the public hospitals. A definition of what hospitals are is necessary in order to frame a law regulating them. In general a hospital should be defined as any building in which two or more sick persons are intentionally placed for diagnosis or treatment.

A law regulating private hospitals was proposed for New Jersey last year but was not introduced into the Legislature. However, a law regulating the nursing homes was introduced and was passed during the closing hours of the Legislature after physicians had been assured that it would not be enacted. While the law was a step in the right direction, it was futile in that it carried no penalty for violation.

The law provided that the Commissioner of Institutions and Agencies should prepare a blank form for recording the data of every nursing home as a basis for licensing it. Commissioner Ellis had prepared an excellent form which was unusually complete and practical. It required information regarding the buildings and grounds, the equipment for giving both personal and professional care, the medical service, with names of both doctors and nurses and the time spent in the care of patient, laboratory facilities, case records, and so on through a long detailed list of inspection items. Its defect is that it does not evaluate the personal skill and character of the physicians.

Dr Sadler said that he had secured information from nearly every state regarding the control of hospitals and had found that very little control was exercised over the private hospitals. The inspections by the American College of Surgeons had been the principal factor in raising the standard of public hospitals and the larger private ones. But forty-seven per cent of patients in the United States are in hospitals of less than fifty beds and these are not inspected or subjected to control.

Dr Sadler said he was heartily in favor of the establishment of an official system for the

inspection and licensing of all hospitals and nursing homes.

Dr Morgan favored the control of the hospitals by an official body. The American College of Surgeons was a select body whose members possessed unusual attainments and usually practiced in large hospitals. But most private hospitals were small and were conducted in communities where surgeons of unusual eminence were not available. Yet every community could produce men of ability and character who could conduct the hospital and perform operations according to high professional standards.

Dr Hammond said that it would not be proper to assume that all private hospitals fail to conform to the highest standards of the profession. He knew private hospitals in which the owners follow the best methods and require all doctors who are associated with them to apply the same high standards. Poor histories was a common defect in the private hospitals, for their managers often seemed to think that the absence of control relieved them from the obligation of making records. One item of official control should be the requirement to keep complete records of all cases. The American College of Surgeons had been the means of educating the doctors of approved hospitals to write histories, and official control of the private hospitals would also produce histories of real value.

The conference unanimously adopted a proposition that the President of each State Society should appoint a representative to serve on a committee of three which should devise a plan for the regulation of private hospitals and should prepare a bill to be submitted to the Legislatures of the three States.

It was decided to hold the next conference in New York City some time during February. The suggestion was made that the topic for discussion be "Expert Medical Testimony."

While the formal transactions of the Convention well justify the holding of the meeting, yet the information gained in informal conversations were also of very great value.

Dr Morgan stated in an informal conversation that the visiting of county societies had been one of his pleasurable duties as president. He had visited one society which had only fourteen members and his was the first visit that a State Officer had ever made to that Society. (See page 1222.)

Dr Morgan also said that the system of public health administration of the State Department of Health provided for a county health officer for every county, paid by the State. These health officers were doing an excellent work in coordinating the public health work of the doctors with that of the State. He also said that in his course of lectures on

therapeutics at the Temple University, he gave talks on the relation of prospective medical men to the county societies and to the public. He considered that students should be informed of the public relations which would be expected of them when they went out to practice.

He stated that the Secretary of the State Society sends a monthly mimeographed letter to the secretary of each county society outlining the salient activities which had developed during the preceding month.

Dr Sharpless told the reporter of the work of the Board of Trustees of the Medical Society of Pennsylvania. He said that the Board

has been in existence for a number of years and that it dominates most of the activities of the Society.

From Dr Reik it was learned that Mrs E C Tanneyville had been engaged as his assistant with the special duties of lecturing to women's clubs. Her work promises to be of great importance in bringing medical education to the attention of the public. The Women's Auxiliaries were especially active in making dates for the lecturer. While she had been on duty only a month, already enough engagements had been made to keep her occupied for the rest of the year. The work promises to be of great interest and value in popular medical education.

### SCHUYLER COUNTY MEDICAL SOCIETY

A special meeting of the Schuyler County Medical Society was held on February 8, 1927, in the Jefferson Hotel, Watkins Glen, N Y at the call of the President, Dr George H King, who occupied the chair. A quorum of the members was present and also, as guests, Dr John W Burton of Tompkins, Dr William C Stewart of Onondaga and Dr George H Dill of Oneida.

Reports were made by Dr Quirk on the desire of this society to have Dr King put upon the list of honorary members, he having passed the age of eighty, and also as Treasurer, concerning the dues paid to him for 1926 and 1927, and also regarding the death of Dr D A Scutt, one of our members, and also the death of Dr G A Mottram, a resident of this village. The visiting physicians were invited to be present at our meetings until they should become members, correspondence being in progress concerning these prospective additions to our number.

A communication from Dr E M Gardiner, Director of the Division of Maternity, Infancy and Child Hygiene of the New York State Board of Health, calling attention to the children's health consultations, was read, and the members agreed to attend these meetings as far as possible.

Dr Allen, as Chairman appointed to form a local committee on cancer, of the American Society for the Prevention of Cancer, asked for suggestions and started a discussion upon the topic.

Dr Bond reported briefly upon the spontaneous recovery of a child from a wound infected with staphylococcus aureus.

Adjournment

The adjourned Spring meeting of the Schuyler County Medical Society, delayed by the illness of the President, was held on July 29, 1927, Dr George H King, President, occupying the chair. A quorum being present and the minutes of the last meeting having been read and approved, a paper was read by Dr Albert Warren Ferris, entitled "Unusual Treatment of a Case of Anemia." After discussion of the paper a report was made upon the State Medical Society Meeting of May 11, by the delegate, Dr Ferris. A report was made on the meeting of the District Branch Medical Society by Dr Quirk.

A report was made by the Treasurer, Dr Quirk, upon the finances of the Society.

The following officers were then elected to the respective position mentioned, for the following year — Dr Oakley A Allen, President, Dr William C Stewart, Vice-President, Dr Frederick B Bond, Secretary, and Dr J M Quirk, Treasurer.

Dr John W Burton was transferred from Tompkins County Medical Society, and Dr William C Stewart was transferred from the Onondaga Medical Society to the Schuyler County Medical Society, and Dr Amos B Edgar was elected unanimously to membership in the Society.

Upon motion, Dr Albert Warren Ferris was elected Delegate to the 1928 meeting of the New York State Medical Society, to represent Schuyler County.

Upon request of the President, Dr Frederick B Bond related several very interesting experiences during his service as Medical Officer in the World War.

Adjournment

# MEDICAL WARES

## DRIED MILK

Milk, like many other food products, is preserved on a commercial scale in two ways 1, by canning, and 2, by drying

Canned milk in condensed and evaporated forms, in which some of its water has been removed, has been on the market for a generation or more, but practical methods of removing all the water and producing a dry product is of recent development. Manufacturers of dried milk have succeeded in preserving the natural taste and qualities of their products to a greater degree than have the producers of the canned forms of milk. Research laboratories are working on the problem, and it is only a question of time when satisfactory milk and cream made from the dried product will be available everywhere. Already dried milk for baby food may be bought at most drug stores.

The limit to the distance that milk can be transported in a fresh state, and to the time that it may be kept unchanged have been almost reached. Only about one-third of the price of milk to the consumer in the large cities goes to the farmer. Another third is expended for transportation and distribution under costly conditions, and it is this percentage of the cost that will enable manufacturers of dried milk to produce a product that will sell everywhere at the price of fresh milk. Bakers already make it their common practice to use dried milk in their bread and cakes. Dried milk will come into common household use as soon as the manufacturers can solve the point of its ready solubility in cold water.

Large quantities of milk are used in industries that have no connection with food. Its casein is made into the strongest known glue, and is formed into an artificial ivory which has all the qualities of gutta serena and celluloid, and is largely used for the barrels of fountain pens. A great economic advance will be made when sections remote from centers of population can turn their milk into dried milk, glue, artificial ivory, and other products which can be stored for indefinite periods of time, and yet can be quickly transported wherever it is needed.

There are two basic methods of producing dried milk. In the roller process two polished steel rollers about two feet in diameter, almost touching each other, revolve about once in four

seconds. They are heated almost to the boiling point. As the milk falls between them, it is dried in a second of time to a thin film which is taken off in a continuous sheet by a knife.

In the spray process, the milk is sprayed into a heated tower in which the dried milk falls in a powder.

Physicians are especially interested in dried milk as a baby food, and they ask specific questions about it.

What is its composition?

The processes of manufacture have been perfected to such a point that every form of milk, from skimmed milk to cream, may be dried without producing an essential change in the chemistry of any constituent. The dried product has the food value,—protein, fat and sugar,—of the milk of which it is made.

What is its solubility?

Dried milk in its present forms is so readily dissolved that a mother can prepare it for food for her baby as quickly and easily as she can prepare any other food.

What is its taste?

Infants like the taste of dried milk, and make no more objection to it than to any other form of bottled food.

What is its digestibility?

Dried milk has all the digestible qualities of boiled milk. Pediatricians now prescribe boiling an infant food in order to cause the protein to be precipitated in flakes instead of masses.

What is the bacterial content of dried milk?

Since dried milk has been heated to the boiling point, it is sterile except as to spores. The bacterial count of the reconstructed milk corresponds to about 50 per c c of whole milk.

What is the vitamin content of dried milk?

Heat at a boiling temperature does not impair the vitamins of milk, but oxidation is likely to destroy its vitamin C,—the anti-scorbutic vitamin. The roller process subjects the milk to oxidation for only one or two seconds. The dried milk will retain its vitamins unchanged for an indefinite period if it is immediately sealed in tin cans containing nitrogen instead of air.

A further point regarding dried milk is that irradiation with ultra-violet rays will activate the milk so that it will have anti-rachitic properties which will be retained in the stored milk.

# THE DAILY PRESS

## THE AVERAGE MAN

Who wants to be an average man? And who is that average man? He is one whose qualities are not spectacular, but are unnoticed among thousands of other persons who have the same characteristics

Every man is a bundle of a hundred or more characteristics. If a person has one quality to a far greater degree than his fellows, that one characteristic receives publicity, or notoriety, in the newspapers, and then the people ascribe all other desirable qualities to him, when in fact he is only an average man in all other respects, with passions and unattained ambitions like the rest of mankind

The average man is a fictitious personage whom no one wants to be. This truly is well expressed by James J. Montague in the New York *Herald Tribune* of June 16 in the following verses

### The Average Man

(Who is found by science to be dull, prejudiced, superstitious, greedy and lazy)

The average man is lazy,  
He won't do what he ought,  
His intellect is hazy,  
He seldom has a thought,  
He has no love of learning,  
He works by fits and starts,  
He has no views concerning  
The sciences and arts

He spurns the pathways leading  
Ambition's arduous way,  
He has no taste for reading  
He's fond of vain display,  
He's filled with superstition,  
He loves to rave and rant  
In idle repetition  
Of other people's cant

He has small education,  
He is a sullen lout  
Whose trifling occupation,  
Is all he cares about,  
And yet he's disputatious—  
He thinks he's always right,  
And ugly and pugnacious  
And spoiling for a fight

The average man is wholly  
Concentered in himself,  
His thoughts are always solely  
On sports, or dames or self,

He's mean and low and hateful,  
He lacks real pep and vim,  
Let's you and I be grateful  
That we are not like him

This is a theoretical discussion of the "average man," but since these articles appeared, the New York daily papers of October 22nd have described an actual "average man." "Mr R L Gray, who owns a one-man clothing store in Fort Madison, was picked as America's 'average man' in an ingenious survey of the country published in *The American Magazine*. Iowa was found to approximate most nearly the 'average' state and Fort Madison the 'average' city. The folk in Fort Madison themselves picked Gray as being most representative of them all, and therefore as being the 'average man'.

"The 'average man' had to talk it over with his 'average' wife and children to decide if they could get along without daddy for a day or so. Also there had to be found an average clerk to take care of the store while Roy was away.

"On the train ride to Chicago with the reporter Gray smoked two average cigars and chatted about subjects of average interest."

Mr Gray was quoted regarding various topics concerning some of which he said

"Locarno pact? What's that?

"Next President? Oh, probably Charley Hughes. Greatest American? Lindbergh undoubtedly.

"Mussolini? He's a good publicity man.

"Flappers? Aw, this chatter about the younger generation going to the bad is silly. The youngsters are all right."

He was then quoted regarding prohibition as saying

"Prohibition? Yes and no. Don't drink myself, so am not specially interested."

That was a sage remark that placed him far above the average man, for he summed up all the philosophies of prohibition. The controversy over prohibition is conducted by two extreme groups. In the first place there are those who are interested in drink to the extent that they wish to have it themselves and insist on their personal rights to use it as an American citizen. On the other extreme there is a group composed of those who think that strong drink is the greatest sin of the age, that it is their duty to eradicate it from the earth. Between

these two groups stands the average man who does not drink himself, and so is not especially interested in either of the other groups

And so the search for the "average man" fails after all, for the one who was exploited is a sage and philosopher possessed of great judgment, and the ability to express himself. But

after all it is not so certain that the "average man" is a dullard, for every person possesses some sort of ability above that of his fellows. And even the one below the average may express a philosophy with a wit and clearness which would be the envy of the average reporter of a daily paper.

---

## HOME CARE OF THE SICK

The New York *Times* of June 1 discusses the remarks of Dr. W. C. Alvarez of the Mayo Clinic at the American Medical Association on the subjects of home diet and home nursing. It says:

"Dr. Alvarez would seem at first sight to be developing a bad case of fundamentalism when he urges the superior advantages, in a good many cases, of that old-fashioned institution, the home, against the modern scientific sanatorium. For those who can afford a first-rate sanatorium he has no suggestions. For the great many who cannot, he believes that the cure will go much better 'in the home of a devoted relative.' This is badly, sadly mid-Victorian. Are there such things as quiet homes to be found in the jazz age? Is the 'devoted rela-

tive' not utterly extinct in an age of self-expression?"

"The speaker evidently believes that the species survives. He assumes that there are still mothers and wives who are willing to take trouble in a sick-room. He further assumes that affection is not necessarily incompatible with intelligence, or, at any rate, that affection plus moderate skill will balance the trained ministrations of nurses. As between a good hospital nurse who will wake an insomnia patient at 7 in the morning in order to make ready for the doctor's inspection and a maiden aunt who will let you sleep till nine, Dr. Alvarez prefers the maiden aunt."

Family physicians will say "Amen" to all this.

---

## HAPPINESS OF THE INSANE

It is the popular opinion that those mentally deranged must necessarily suffer continual mental torments. This opinion has been derived largely from the symptoms of acute mania—a condition seen but seldom. As a matter of fact, a derangement of mental faculties lessens the capacity of suffering, as it does other psychological acts. The New York *Sun* of August 25 has a news item regarding this point as it quotes from an article in *Psychology* magazine, by Dr. George A. Smith, Superintendent of the Central Islip State Hospital. The *Sun*, quoting Dr. Smith, says:

"It is not necessary to pity the insane, sixty per cent of them are far happier than their normal brethren.

"The sane person even though he possesses happiness is always confronted by struggle, by the necessity of solving problems. He must face reality. The insane person has escaped reality. Insanity really means escape—escape into phantasy. The insane person is living in a world of his own delusions, and in the ma-

jority of cases they are pleasurable delusions. It's a saying among my doctors that the happy people are inside the institution, the unhappy outside.

"Many of our 'trusties,' dementia praecox cases, with certain fixed delusions but otherwise apparently normal, are among the happiest people I have ever seen. They regard the institution as home. If we opened the doors and told them to go they wouldn't budge."

People are beginning to realize that an insane asylum is in fact a hospital for treating mental cases, and they are seeking treatment in increasing numbers. One great reason in producing the increase in the number of patients is the fact that the patients are happy and contented while they are under treatment, and are conscious of their progressive improvement.

Physicians have the responsibility of teaching the people regarding the manner of treating patients in the mental hospitals, and the mode of life that the patients lead.

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

- POTASSIUM AND TARTRATES** A Review of the Literature on Their Physiological Effects By RALPH W WEBSTER, Ph.D., M.D. With a digest and bibliography of the literature by W A Brennan, A.B. 12mo of 168 pages. Chicago, The Commonwealth Press, 1927. Cloth, \$2.50.
- MANUAL OF DISEASES OF THE EYE FOR STUDENTS AND GENERAL PRACTITIONERS** By CHARLES H MAY, M.D. 12th Edition, revised. 12mo of 445 pages, with 374 original illustrations. New York, William Wood and Company, 1927. Cloth, \$4.00.
- PHYSICAL DIAGNOSIS** By RICHARD C CABOT, M.D. 9th Edition, revised. Octavo of 536 pages, illustrated. New York, William Wood and Company, 1927. Cloth, \$5.00.
- COMPENDIUM OF REGIONAL DIAGNOSIS IN AFFECTIONS OF THE BRAIN AND SPINAL CORD** A concise introduction to the principles of clinical localization in diseases and injuries of the central nervous system. By ROBERT BING. Translated from the sixth German edition by F S Arnold, B.A., M.D. 3rd Edition, revised. Octavo of 204 pages, with 102 illustrations. St. Louis, C V Mosby Company, 1927. Cloth, \$6.00.
- THE MEDICAL DEPARTMENT OF THE UNITED STATES ARMY IN THE WORLD WAR.** Prepared under the direction of Maj Gen M W IRELAND. Volume II Administration American Expeditionary Forces. By Colonel JOSEPH H FORD, M.C. Royal octavo of 1123 pages, illustrated. United States Government Printing Office, 1927.
- MEDICAL CLINICS OF NORTH AMERICA** Volume 11, Number 2. September, 1927. (St. Louis Number). Published every other month by the W B Saunders Company, Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00 net, paper, \$12.00 net.
- A TEXT-BOOK OF HISTOLOGY** Arranged Upon an Embryological Basis. By Dr FREDERIC T LEWIS and Dr J L BREMER. This is a revision of the second edition of Lewis and Stohr's Textbook of Histology, based on the fifteenth German edition of Stohr's Histology. Octavo of 551 pages, with 485 illustrations. Philadelphia, P Blakiston's Son & Company, 1927. Cloth, \$6.00.
- HOSPITAL LAW** By JOHN A LAPP and DOROTHY KETCHAM. Octavo of 557 pages. Milwaukee, Wisconsin, The Bruce Publishing Company, 1926. Cloth, \$8.00.
- SURGICAL CLINICS OF NORTH AMERICA** Vol 7, No 1. February 1927. Cancer I. Vol 7, No 2. April, 1927. Cancer II. Vol 7, No 3. June, 1927. Cancer III. (Chicago Number). Published every other month by the W B Saunders Company. Philadelphia and London. Per Clinic Year (6 issues). Cloth, \$16.00 net, paper \$12.00 net.
- FISTULA OF THE ANUS AND RECTUM** By CHARLES JOHN D RUECK, M.D. Octavo of 318 pages, with 66 illustrations. Philadelphia, F A Davis Company, 1927. Cloth, \$3.50.
- FEEDING AND THE NUTRITIONAL DISORDERS IN INFANCY AND CHILDHOOD** By JULIUS H HESS, M.D. 5th Edition, revised. Octavo of 566 pages, illustrated. Philadelphia, F A Davis Company, 1927. Cloth, \$4.50.
- SURGICAL DISEASES OF THE GALL-BLADDER, LIVER AND PANCREAS AND THEIR TREATMENT** By MOSES BEHREND, A.M., M.D. Octavo of 278 pages, illustrated. Philadelphia, F A Davis Company, 1927. Cloth, \$4.00.
- CANCER CONTROL.** Report of an International Symposium Held under the Auspices of the American Society for the Control of Cancer, Lake Mohonk, New York, September 20-24, 1926. Octavo of 336 pages. The Surgical Publishing Company of Chicago, 1927.
- THE SCIENCE AND PRACTICE OF SURGERY** By W H C. ROMANIS, M.A., M.D., and PHILIP H MITCHNER, M.D. Two Volumes. Vol 1—General Surgery. Octavo of 795 pages, with 666 illustrations. Vol 2—Regional Surgery. Octavo of 955 pages, with 666 illustrations. New York, William Wood and Company, 1927. Cloth, \$12.00.
- RECENT ADVANCES IN BIOCHEMISTRY** By JOHN PRYDE, B.Sc., M.Sc. Octavo of 348 pages, with 38 illustrations. Philadelphia, P Blakiston's Son & Company, 1926. Cloth, \$3.50.
- BLOOD-PRESSURE ITS CLINICAL APPLICATIONS** By GEORGE WM NORRIS, A.M., M.D., HENRY C BAZETT, M.B., and THOMAS M McMILLAN, A.B., M.D. 4th Edition, revised. Octavo of 387 pages, illustrated. Philadelphia, Lea and Febiger, 1927. Cloth, \$4.50.
- SURGERY ITS PRINCIPLES AND PRACTICE.** For Students and Practitioners. By ASTLEY PASTON COOPER ASH-HURST, A.B., M.D. 3rd Edition, revised. Octavo of 1179 pages, illustrated. Philadelphia, Lea and Febiger, 1927. Cloth, \$10.00.
- A TREATISE ON ORTHOPAEDIC SURGERY** By ROYAL WHITMAN, M.D. 8th Edition, revised. Octavo of 1051 pages, illustrated. Philadelphia, Lea and Febiger, 1927. Cloth, \$9.00.
- MODERN MEDICINE** Its Theory and Practice in Original Contributions by American and Foreign Authors. Edited by Sir WILLIAM OSLER Bart., M.D. Third Edition, thoroughly revised. Re-edited by Thomas McCrae, M.D. Assisted by Elmer H Funk, M.D. Volume 5. Diseases of the Blood—Diseases of the Lymphatic System—Diseases of the Ductless Glands—Diseases of the Urinary System—Vasomotor and Trophic Disorders—Diseases of the Locomotor System. Octavo of 948 pages, illustrated. Philadelphia, Lea and Febiger, 1927. Cloth, \$9.00.
- A TEXT-BOOK OF THERAPEUTICS** Including the Essentials of Pharmacology and Materia Medica. By A A STEVENS, A.M., M.D. 7th Edition, reset. Octavo of 758 pages. Philadelphia and London, W B Saunders Company, 1927. Cloth, \$6.50.
- BRONCHOSCOPY AND ESOPHAGOSCOPY** A Manual of Peroral Endoscopy and Laryngeal Surgery. By CHEVALIER JACKSON, M.D. 2nd Edition, reset. Octavo of 457 pages, with 179 illustrations. Philadelphia and London, W B Saunders Company, 1927. Cloth, \$8.00.
- CLINICAL DIAGNOSIS BY LABORATORY METHODS** A Working Manual of Clinical Pathology. By JAMES CAMPBELL TODD, Ph.B., M.D. and ARTHUR HAWLEY SANFORD, A.M., M.D. 6th Edition, revised. Octavo of 748 pages, with 346 illustrations. Philadelphia and London, W B Saunders Company, 1927. Cloth, \$6.00.

# BOOK REVIEWS

**IMMUNITY IN SYPHILIS.** By ALAN M. CHESNEY. Octavo of 85 pages. Baltimore, The Williams and Wilkins Company, 1927. Cloth, \$2.50. (Medicine Monographs Volume XII.)

This monograph reviews the subject of immunity in syphilis as set forth in recent literature in great detail. As a result of this critical inquiry, the conclusions are in the main negative, except that there is an acquired resistance, more or less complete, in both experimental animals and man to secondary syphilitic infection after the primary infection has been present a few weeks. Whether this is due to an uncured latent focus or to an acquired immunity which persists in the absence of the disease, is left an unsettled question by the author, but the weight of evidence seems to be with the latter premise.

The book is well written and is a worthwhile review of the modern literature on syphilitic immunology.

JOHN C. GRAHAM

**TROPICAL SURGERY AND SURGICAL PATHOLOGY.** By KARUNA K. CHATTERJI, F.R.C.S.I. With a foreword by Sir R. HAVELOCK CHARLES. Octavo of 244 pages, illustrated. New York, William Wood and Company, 1927. Cloth, \$6.00.

The author, who has had a wide experience in some of the larger hospitals in India, and Europe, clearly describes the surgical conditions peculiar to the tropics. The difference in predisposition to disease of the natives of India and of the newcomers is discussed at length. The surgical diseases due to filarial infection, amebiasis are clearly presented. The various forms of granulomata as they occur in the Far East are excellently illustrated. There is also a description of the several ilio-inguinal forms of swelling, their progress and growth as they occur in the tropics. The various forms of hernia are well described, and the drawings are wonderfully clear.

E. H. NIDISH

**A MANUAL OF GYNECOLOGY.** By JOHN OSBORN POLAK, M.Sc., M.D. 3rd Edition, thoroughly revised. Octavo of 402 pages, illustrated. Philadelphia, Lea and Febiger, 1927. Cloth, \$5.00.

This edition of Polak's well known and justly popular manual has been revised and made to include all the more important recent additions to the general subject of gynecology—such as symptomatology, pathology, diagnosis and treatment. A brief summary on the glands of internal secretion and their relation to the sexual organs has been added.

As in former editions of the Manual, the subject matter is very well arranged, giving in outline only the salient facts. It has been "boiled down" remarkably well. Nothing has been "padded." All theoretical discussions have been omitted. Only a few of the well known successful operative procedures have been described. All undergraduate students and many practitioners have no need for a Manual of operative procedures. These, therefore, have purposely been omitted.

After "all is said and done," diagnosis is the most important phase of any department of medicine and this Manual fulfills the need for gynecology very admirably.

H. B. M.

**PULMONARY TUBERCULOSIS.** By G. T. HEBERT, M.A., M.D. 12mo of 212 pages. New York and London, Longmans, Green and Company, 1927. Cloth, \$3.00.

This two-hundred page octavo size book is intended by the author "chiefly for senior students studying for

examination or taking a post-graduate course, and for the general practitioner. The earlier chapters are intended for the student beginning his clinical course."

It is with much modesty these intentions are declared. Any physician mastering all the knowledge therein contained and devoting some time to the practical application of it, will be possessed of great skill in the care of tuberculous patients.

No special original matter is introduced. The finer, still unsettled points of this disease are not dwelt upon but no essential matter is omitted. On the elements entering into the diagnosis and care of these patients, the author places a proper evaluation, crediting history, physical and special examinations, X-ray and other laboratory work justly but emphasizing the need of *all* and *thoroughness* in their use.

In compressing so much into small space, the author has not omitted important parts, but has succeeded by logical arrangement in groups and has explained it all in exact nomenclature and in a style clear, forcible and pleasing.

Prognosis for the patient in England is apparently not as rosy as many of our books tell us it is in this country. However, those here who have charge of many moderately and far advanced cases have hearts very often sad and discouraged. Treatment in this book is not neglected and plans along the lines of which the real cure must be sought are indicated.

Every doctor whose work includes care of patients with pulmonary tuberculosis will be made glad with the reading of this book.

T. A. MCG

**MANUAL OF BACTERIOLOGY.** By ROBERT MUIR, M.A., M.D., and the late JAMES RITCHIE, M.A., M.D. 8th Edition. Revised with the co-operation of CARL H. BROWNING, M.D., and THOMAS J. MACKIE, M.D. 12mo of 821 pages, illustrated. New York and London, Oxford University Press, 1927. Cloth, \$4.75. (Oxford Medical Publications.)

Perhaps the best commentary one can make upon this text-book is that it was first published in 1897 and now appears in its eighth edition. A text-book must have merit to survive for thirty years.

Prof Ritchie having died, Prof Muir has been assisted in the revision of this edition by Profs Browning and Mackie, who are well known in this country for their researches.

This edition has been brought as completely up-to-date as possible. One notes that much space has been given to description of technical methods which are steadily improving. Recent advances in knowledge of bacteriophage, tularemia, Malta fever, Rickettsia and encephalitis are included. The pathogenic fungi and protozoa are adequately described.

E. B. SMITH

**A MANUAL OF MATERIA MEDICA FOR MEDICAL STUDENTS.** By E. QUIN THORNTON, M.D. Second Edition, thoroughly revised. Octavo of 384 pages. Philadelphia, Lea and Febiger, 1927. Cloth, \$4.50.

This second edition of Dr Thornton's manual is in accord with the new pharmacopoeia, but, in other respects, has all the characteristics of its predecessor—accuracy, sufficiency, brevity and a general utility that makes it a good book to possess. It is refreshing to note the tendency in the modern books on *Materia Medica* toward an elimination of that long list of purely empiric remedies that cluttered up the pages of the books of yesterday! But one wonders if we are introducing in their place an equally long list of synthetics.

M. F. DE L.

# OUR NEIGHBORS

## PRESIDENT'S ADDRESS, MEDICAL SOCIETY OF PENNSYLVANIA

The address of Dr Arthur C Morgan, president of the Medical Society of the State of Pennsylvania before the general meeting of the society on October 4, at Pittsburgh, is printed in the October issue of the *Atlantic Medical Journal*, the organ of the State Society. It is interesting to the physicians of New York State because it reveals the ideals and realizations of the leader of the medical profession of a sister state.

Concerning the meetings in the Councilor Districts, which are analogous to the District Branches in New York State, Dr Morgan says

"The attendance, interest, scientific programs, and good-fellowship that have marked the many councilor district meetings at which it has been our good fortune to be present, serve to indicate the live appreciation by our membership of the good that results from contact with their fellows. The by-laws stipulate that one or more district meetings shall be held each year. The routine work connected with the notices and details are well entrusted to our State Society secretary who performs these duties with promptness and dispatch. Some geographical sections hold annual clinic days, and these likewise are largely attended. A whole day spent in this laudable manner brings great reward. It may be well, however, to bear in mind that the councilor district meetings should not be neglected, but that the same effort put forth will bring equal results in each instance."

Concerning the smaller county societies the President says "The populous and well-organized county society is under obligation to its less favored neighbor. In this State there are societies with small membership adjacent to those rich in numbers and influence but unable to undergo the expense of providing programs. It may be that arrangement with the stronger unit could be made for printing the programs and personal items of the smaller body, and the circulation of the combined programs would serve the double purpose of a wider range of dissemination and a reminder to look after the needy one. Another way by which the smaller county societies may be helped would be by the publication of a bulletin issued at regular intervals from the office of the State Society secretary, incorporating the programs and items of interest from all societies that do not print their own local bulletin. This could be made a clearing house in many respects, and would lead to interchange of speakers, programs, and suggestions that would justify the moderate expense involved."

The President discussed the Tri-State Conference as follows

"Three years ago an organization was effected for quarterly conferences between the chief officers of the State Societies of New Jersey, New York, and Pennsylvania, with much good resulting therefrom. We are honored by having at this session of the Society several of the officers from those and other States as our guests, and we here-with tender to them a cordial welcome and greeting. Your House of Delegates has properly agreed to care for the financial outlay necessary for the officers of this State to function at these conferences. We can say with candor that the efforts put forth in this direction will bring rich return, for there has come a clarity of understanding, a mutual pooling of interests, unity of purpose, and cooperation that will serve to promote close association between the States represented which, in turn, will be of immense value when it becomes necessary to advocate new, or change old methods of working" (See page 1214.)

The no diphtheria campaign is described as follows

"Much progress has been made in the fight for diphtheria prevention, and the slogan "No diphtheria by 1930" is not an idle dream. To Cambria County goes the honor for having shown the greatest interest in this work. Credit is also given to cooperation by the State health authorities. Preliminary education of the public through the Red Cross and other organizations paved the way for the success of the campaign. Toxin-antitoxin was furnished by the Health Department at Harrisburg. What has been done by Cambria County can be repeated elsewhere. They report as follows: "The Red Cross does the detail work, collects the fees, the State Health Department furnishes the toxin-antitoxin, but our members are paid \$25 a day for their work. Members are called in alphabetical order and given an opportunity to do immunization work. It is team work that has made our campaign a success."

Plans to increase the scope of the *State Journal* are described as follows

"The *Atlantic Medical Journal* continues to hold high place in the ranks of state journals, under the watchful care and guidance of Editor Hammond. Negotiations are under way looking to a hoped-for inclusion of other coast states in enlarging the scope of the *Journal*, as indicated by its title "Atlantic." It is suggested that prompt record of events makes good reading matter, but when contributors delay reports for many weeks

(The Safe Milk)

# IDEALLY ADAPTED

FOR THE

# MARASMIC INFANT!

*P*EDIATRISTS generally agree that the food given the *marasmic* infant must be exceptionally concentrated because the vigor and stomach capacity are both inadequate for the ingestion of large volumes of food. The food, too, must be of such a balance that it will supply the needed nutrients in proper proportion. The most important consideration is the selection of a food that is readily digestible since the digestive capacity is unquestionably subnormal.

This combination of a concentrated food of proper balance, high caloric value, which is readily digestible and completely assimilable is available to the Pediatrician in DRYCO, the safe milk in powder form. By virtue of the fact that the quantity of water may be diminished a concentrated diet of high caloric value may readily be obtained. The fineness and softness of the DRYCO curd assures its maximum assimilation and absorption with a minimum of digestive effort. In view of its palatability *marasmic* infants readily adapt themselves to DRYCO, showing at the same time, a marked improvement in appetite and weight.

Address \_\_\_\_\_

(Continued from page 1222)

they cannot expect to secure space that belongs to more recent material. A good county society reporter is of great value in the dissemination and exchange of information through the *Journal*, that serves to act as a clearing house for the benefit of our entire membership.

"Through the courtesy of the editor of the *Atlantic Medical Journal* your president will have the privilege of using a page in each issue. Our purpose is to convey to the membership at large such matters as it is deemed important to present promptly rather than to defer until the next annual session. We have at this time, therefore, discussed only a few of the more important activities of our Society, and will invite your attention to the monthly letters that will appear in the *Journal*."

The work of the Woman's Auxiliary is commended as follows:

"The Woman's Auxiliary has made commendable progress during the past year. The organization is now on a working basis, is self-supporting, its meetings are well attended, new county branches are being started, and there is evidence of a healthy growth of sentiment in this direction. We are greatly indebted to the women for their splendid response to our requests, when pernicious legislation threatened to carry, in conducting effective campaigns among their members and friends that added to our strength and defeated many dangerous bills."

Dr. Morgan has this word of warning against certain organizations:

"Caution suggests investigation of the merits of organizations that seem to have the welfare of the people for their end and aim. Well-established societies, such as the Red Cross, may be well supported, and cooperation freely accorded. Health studies, surveys, contraception teaching and the like should be shunned. The prime force back of many of these movements will be found to be chronic or professional office holders; notoriety seekers, and those who eke out a living by feeding at the public trough."

## MEDICAL EDUCATION OF THE PUBLIC

The October issue of the West Virginia Medical Journal has the following editorial description of a plan of the State Medical Association to supply speakers at luncheon clubs throughout the state:

"A new method or plan of getting the message of scientific medicine across to the lay public has been recently worked out by the Committee on Public Relations of the West Virginia State Medical Association. The plan is unique in every respect and deserves the whole-hearted support of every member of the state society."

(Continued on page 1225—adv xvii)

(Continued from page 1124—adv xvi)

"According to Dr J R Shultz of Charleston, chairman of the professional relations committee, the new method embraces every luncheon club in West Virginia and the message of scientific medicine will be "put over" by some twenty or thirty "doctor speakers" in the state association. The business of recruiting these "doctor speakers" has already been started and is meeting with splendid success.

"According to details already worked out, each luncheon club program committee in West Virginia will shortly be notified that our state medical association has available speakers whose services can be obtained for the asking. The notification will set forth that the speakers have already prepared talks on the relation of the physicians and the public and will ask that all requests for speakers be sent to the executive secretary at Charleston.

"It is the hope of the committee on professional relations that about twenty-five speakers can be obtained in the medical ranks and that they will be located in the various cities and towns throughout the state. When this is accomplished, if a request for a speaker is received from the Spencer Rotary Club, a speaker from Parkersburg will be notified to attend, if from Princeton, a speaker from Bluefield will be notified to attend, but never, according to Dr Shultz, will a speaker be allowed to talk in his own home city.

"The results to be accomplished from such a plan are two-fold. In the first place the message of medicine to the lay public will be handed out to select audiences throughout the state. In the second place, the newspapers that cover the luncheon club meetings will carry the message in their columns the next day to their general readers. Surely such a plan should be given the unqualified support of the members of the association."

The plan of presenting medical subjects to lay audiences appeals to the physicians of New York State and has been in operation unofficially for years. The experience of New York State is that physicians are well received in their own communities. In fact, they resent the importation of an outside speaker when a local one is available. It is not quite clear why a speaker will not be allowed to talk in his own home city in West Virginia.

### MALARIA DISAPPEARING

Can malaria be prevented? The medical profession of Georgia believes that its prevention is not only a possibility but is an actuality in that state. Read the following editorial in the October issue of the *Journal of the Medical Association of Georgia*.

### PATCH'S FLAVORED COD LIVER OIL

At the Sesquicentennial Exposition held in Philadelphia last year, the E L Patch Co was awarded the gold medal for "excellence of product."

This award is only one of the various forms of recognition which our product has received.

The recognition given to our product by the medical profession, after five years of clinical experience, constantly reminds us of our great responsibilities.

Here are a few reasons why Patch's Flavored Cod Liver Oil is dependable.

It is made in our own plants along the North Atlantic Coast, from FRESH LIVERS.

Every lot is biologically assayed. The vitamin potency is guaranteed.

The dose is small—a half teaspoonful for children or a teaspoonful for adults three times a day.

It is pleasantly flavored. Your patient will appreciate this feature.

Let us send you a trial bottle of this "Gold Medal Cod Liver Oil."

Taste it! You'll be surprised.

(Continued from page 1225—adv xvii)

"It is evidence of the progress made by preventive medicine in these parts that a disease, which a few years ago was so prevalent that some communities looked forward to periodic chills and fever as a matter of course, should now deserve the above title by Dr C C Bass in the April number of the *New Orleans Medical and Surgical Journal*

"He states that, whereas ten years ago the wards of the Charity Hospital of Louisiana at New Orleans were seldom without numbers of patients with malaria, at the present time such cases are so rare that it is difficult to find sufficient material through the year to demonstrate the infection to the medical students. He notes that among the factors contributing to the elimination of the disease are first, the clearing and draining of lands for agricultural purposes, second, the widespread knowledge that it is transmitted by mosquitoes and the measures taken to prevent infection through their bites, and third, the intensive and intelligent use of quinine

"A fourth and essential factor, universally recognized, is the contribution made by Dr Bass himself as head of the National Malaria Committee, and his success in culturing the plasmodia in artificial media

"An idea of the extent of the decline is given by Dr F M Johns who in discussing the subject stated that among two hundred fifty-nine smears examined for malaria in a year's time only one showed the plasmodia. In three years at Wesley Memorial Hospital in Atlanta only three cases were found in the laboratory

"These findings and the well-known fact that practicing physicians generally are seeing so much less of the infection should remind us that the essential factor in diagnosis is the demonstration of the parasite in blood smears

"Our State Board of Health laboratories are well equipped to render this service

"It is to be hoped that through the co-operation of the public health officials and the practitioners of the state it will not be long until that disease that at one time was a scourge in many southern localities will be a thing of the past"

## ORGANIZATION WORK

Some counties of New York State have so few physicians that their County Medical Societies have a struggle for existence, but that condition is still more acute in some of the southern states. The August *Journal* of the Tennessee State Medical Association suggests a remedy in the following editorial

"The results from combining a number of  
(Continued on page 1227—adv xix)

(Continued from page 1226—adv XVIII)

small counties into one medical organization are so very excellent that we would now urge small counties which are functioning independently to combine with other adjoining counties for the purpose of programs only

"It is exceedingly rare for a county with a small number of doctors to have a good medical organization. A slight division of opinion among six or eight doctors is enough to destroy the organization, whereas if the small number of doctors in one county combine with a small number in another county the differences are obliterated by numbers and the whole number enters into the spirit of the organization whole heartedly. We would heartily recommend this plan for the consideration of all small counties

"All of the large blocks of counties that were unorganized two months ago are organized today. There are, however, several counties still unorganized. Some of the doctors of these unorganized counties are members of societies of adjoining counties

"Our investigations have revealed that there are a number of doctors residing in counties that are organized who are not members of a county society. We wish to urge that effort be put forth to bring into organized medicine every eligible white doctor in the state. This office will put forth every effort in cooperation that is possible. Our membership today numbers 1542. We wish to build it up to at least 1700 in the next two or three months."

## COUNTY MEDICAL SOCIETY REPORTS IN NEW JERSEY

New Jersey seems to be far ahead of New York State in the record of the *Journal* of the Medical Society of New Jersey in securing reports from the County Medical Societies. The annual report of the editor, Dr. Henry O. Reik, printed in the supplement of the August *Journal*, says

"The county society reports have become a valuable asset to the *Journal*. We are able to report that practically every county medical society meeting held in this state during the past two years has been published in the *Journal* within a month after the date of its deliberations. We know of no other state journal that can touch that record, and right here we desire to express our hearty appreciation of the work of the reporters of the county societies and to thank them for the manner in which they have complied with our requests for prompt and comprehensive reports of proceedings. The literary, scientific and educational value of these reports varies

### A STATE FAIR EXHIBIT

The Nebraska State Medical Association put on an exhibit at the State Fair, according to the following editorial description in the October issue of the Nebraska State Medical *Journal*

"The prevision of the Council who sponsored the idea of a health exhibit at the State Fair is justified by the results and already plans are in the making for a better and larger exhibit for the 1928 State Fair. It will be recalled that the House of Delegates at the last annual meeting,

on recommendation of the Council, appropriated \$500 for an exhibit at the State Fair and appointed a committee to develop and carry out the intent of the motion. The exhibit which occupied two adjoining booths consisted of pathological specimens from Creighton and Nebraska State Universities Medical Colleges, the paleopathological collection of Dr F B Young, of Gering, placards from Creighton and Nebraska Universities and the State Bureau of Health, and a collection of biological products from Mulford.

"Lectures were given almost continuously to groups of Fair visitors who by their attentiveness indicated an interest in the matter presented much greater than had been anticipated. Dr E. R. Hays, Falls City, Dr F B Young, Gering, and C E Leisure, senior at Creighton University College of Medicine, gave the talks and it is estimated that five thousand people eager for information were reached. The speakers dwelled on tuberculosis, typhoid, diphtheria, scarlet fever, focal infections, rickets and other food deficiency conditions, proper diet for children and adults, open air and sunshine, insect pests, and vaccination against small pox, diphtheria, scarlet fever and typhoid fever. Several thousand folders entitled 'Keep Well' furnished by the Nebraska State Medical Association, were distributed. Valuable assistance was given daily by two nurses furnished by the Nurses Club of Lincoln."

## MEDICINE AT PUBLIC HEALTH CENTERS

The October issue of the *Illinois Medical Journal* comments editorially on the address of Dr. Carlown Brooks before the conference on Public Health held in Chicago on March 24, under the auspices of the American Medical Association and reported in the July 2nd issue of the *A M A Journal*. The editorial quotes Dr. Brooks as follows:

"The medical profession devotes voluntarily from 25 to 45 per cent of its time to unremunerated personal charities, mostly to that large and generally inarticulate mass of unfortunates that are the secret wards of every medical man. Misunderstandings between the profession and social activities along the line of public health have almost without exception originated when physicians have been asked to abrogate and to forget their scientific training or when their code of ethics has been ruthlessly ignored. There is no more reason why medical ethics may not be applied in public health than in any other specialty in the medical profession. No efforts at progress will succeed until lay organizations are brought to realize that the principles that have made modern medicine and the true physicians of all times, will be upheld.

"That the family physician has no quarrel with public health activities save in that as a scientist his skill and knowledge demand that he shall protest the substitution of amateur manipulation for skilled professionalism, is a point seldom made clear.

"Has the family physician cause for resentment? Examine the activities of public health centers and clinics and those of the family physician."

Commenting on these remarks the editorial continues:

"Co-operation of honest lay bodies is welcome to all physi-

cians. But the tendencies of such organizations to put 'the cart before the horse' must be suppressed. For in every angle of the work the doctor must dominate. Such domination has made medical progress possible, and those professional standards that have literally 'made medicine' must prevail. Else there shall be chaos and loss.

"Public and private medicine must work hand in hand. There is no other sane or successful way to success. The physician in close contact with his patient is the most successful teacher of public medicine. After all the physician is the mouthpiece of medical science and when any influence belittles the teacher it destroys the doctrine. Public medicine to succeed needs the endorsement of private medicine and must not for an instant attempt to either underestimate the influence of physicians with patients, difficult as that is for a lay person to comprehend, nor to discount its value.

"From experience the medical profession believes that a license to practice should be granted only after four more years of study in an accredited school superimposed on a preliminary education of no mean extent or small cost. The public differs, principally because the public does not know. And consequently all manner of cults are backed annually by well-intentioned persons of all sorts, from the clergy to philanthropists and even financiers of repute.

"A remedy for the deplorable invasion of the terrain of medicine by the misguided ignorant public health movements lies in the work of state, county and district medical societies. In the language of the street, 'It is up to them.' Each organization and each member of these organizations needs to don sword and buckler, and get into the combat of education of the general public as to the difference between safe and sane and skilled medical service, and the visionary, half-baked, and often unethical care that emanates from lay practice and dictation of medicine."

## PHOTOTHERAPEUTICS OF DERMATOLOGY, ITS BASIC UNDERLYING PRINCIPLES\*

By HERMAN GOODMAN, B.S., M.D., NEW YORK, N Y

I HAVE taken this opportunity to portray more or less graphically, the subject matter of the title. To begin with, I mention Newton's primary experiment with the ordinary glass prism. In a darkened room, a hole is made in the shutter, and the path of the beam of light is interrupted by a prism, held point down. On the wall, the beam of white light is decomposed into the primary colors of the spectrum from violet to red. The violet is refracted more than the red

light ranges from 7700 in the red to 4300 in the beginning of the violet. The violet ends at 3900 A u.

FIG. 1—Dispersion of white light through a glass prism into the spectral colors from violet to red (visible)

In order to show that the prism does not produce the colors, one band of the decomposed light, for example, the green, is allowed to pass through a hole in a piece of cardboard, and through a second prism. No further decomposition of the green band is seen. Light of a definite position in the spectrum and hence of a definite range is called monochromatic.

I give the range of visible light in Angstrom units. It is sufficient to say that an Angstrom unit measures one two-hundred and fifty four millionths of one inch in length. Visible

FIG. 2.—Showing the monochromatic nature of light radiation after dispersion.

If one substitutes a prism of quartz for the glass prism, one may get effects which disclose the presence of zones of radiation beyond the visible zone. It suits our purpose at this time to mention the infra red zone, which lies beyond the red end of the visible spectrum. But of greater importance to us in therapeutics is the opposite end of the spectrum, the end beyond the violet, known as the ultraviolet. The physicist has divided the regions of the ultraviolet into the near, middle and far ultraviolet.

FIG. 3—Range of visible light in Angstrom units

As one more interested in physiology, it has occurred to me to divide the ultraviolet in another way. I have taken two set places in the ultraviolet, one the limit of natural sunlight which is at 2900 A u, and the second is the conventional barrier of glass to the ultraviolet which is about 3200 A u. For purposes then of physiology, we may divide the ultraviolet

\* Read before the Section on Dermatology and Syphilology of the Medical Society of the State of New York at Niagara Falls, N Y, May 11 1927

ducing diet. This same zone is the one which affects the calcium metabolism of pregnant women. And it is in this self same zone that some of the lines are present which act on the precursor of the antiricketic vitamin present in non-active cholesterol.

I mention a few sources of light in common use. The open and enclosed carbon arc, the magnetite arc developed by Steinmetz, the mercury arc, and the glass enclosed incandes-

Fig. 7—Chickens of the same hatch originally but the stunted one brought up under glass (after Bovie)

cent bulb, the Edison carbon filament, the tungsten and the gas bulb.

My next picture gives the starting characteristics for the mercury vapor arc in quartz as sold for therapeutic purposes. It should be noted that only after five minutes does the emission resemble full emission for unit of time. By this I mean that if one were to esti-

use. It is true that there is a deterioration and that this effects the emission of the ultraviolet to upward of fifty per cent, in the ultraviolet zone which I have called the extravital, and to a degree the vital ultraviolet emission is likewise reduced. But with the modern mercury vapor arc in quartz as sold to physicians improvements have been made which make their effective life much longer than the previously published figures indicated. I no longer stress this factor although a chart showing the deterioration according to the older estimates is worth studying.

The use of carbon arc lamps was one of the earliest procedures in phototherapy, and Finsen based his work on such a source. We have advanced far beyond the Father of Modern Phototherapy. I will merely mention that in the use of the carbon electrode we are today beyond the carbon, and in fact our modern apparatus does not utilize the arc. Today we utilize the emanation of the core or the impregnation of the carbon. At this writing we use the flame lamp rather than the crater. In the ordinary lamps we must have the proper relationship between the diameter of the carbon, impregnated or cored electrode, the current in amperes, and the voltage across the arc. When these factors are the proper ones we can and do select the emanation we desire. We can at will then give radiation rich in one or another zone of the visible, the intravital, the vital, or the extravital ultraviolet. We can

Fig. 8—Air cooled mercury vapor arc in quartz therapeutic model—a, at ignition, b 20 seconds later, c, after 1 minute, d after 5 minutes, e, after 10 minutes, f after 30 minutes. Slit opening, time of exposure, and distance constant.

mate the starting characteristics and allow for the diminished energy, one could by exposing the ignition for 100 seconds instead of ten seconds get a spectrogram which is exactly that of the lamp after ten minutes operation. Such spectrograms are given. Incidentally, if one takes cognizance of the rules of physics, one finds that the feature of distance has been overstressed in the literature. Allowing for time, one can get practically the same spectrogram at 10 feet that one does at 10 inches.

Much has been written regarding the deterioration of mercury arc in quartz burners with

get effective limits as in sunlight, or we can encroach on the ultraviolet absent in the sun's emission as it reaches this earth. We show the qualitative emissions for the sun, and the various carbons as prepared by the National Carbon Company of Cleveland, Ohio, U. S. A., under the names of Therapeutic A, B, C, to K, and for comparison the line spectrum of an iron arc and the scale in Angstrom units. The strong group of lines about 3860 Å are those of the cyanogen band due to the combustion of the carbon with the nitrogen. These lines are in the intravital ultraviolet and so close to the

The other countries of the world have their manufacturers at work on the problem of what I have termed "Prescription Carbons" and we

FIG. 11.—Qualitative spectrograms of iron arc, and impregnated carbons from "A" to "K."

outside the vital ultraviolet, it would appear that this feature is not of decided benefit in our concept of vital ultraviolet.

The two most commonly used impregnated carbons at present are the "White flame" and the "Blue flame." The white flame gives much energy in the infra red (heat) visible zone, and the ultraviolet to about 2900 A.u. Comparatively little energy of wave lengths shorter than 2900 A.u. is emitted. The greatest energy emission is in the short visible and in the ultra-

will have the selection of practically any zone of emission in excess or any combination of zones. In time, the physician will have command of the emission at the source. He also will have command of what range, and how much of that range will reach his patient. By the use of filters, we will be able to limit the radiation to predetermined bands.

A number of filters are available. The qualitative limits of a clear Corning glass are practically the equivalent of quartz. Other filters

FIG. 12.—Qualitative limits of a number of ultraviolet filters compared to window glass.

violet as present in sunlight. The blue flame gives off its energy through the visible zone and the ultraviolet to 2300 A.u. Properly utilized, one gets an erythema with blue flame electrodes. In some respects and at suitable amperages, the blue flame emission is somewhat similar to the emission of the mercury vapor arc in quartz, although greater energy consumption is required. Uses in medicine

of ultraviolet in the vital zone are demonstrated by their qualitative spectrograms as compared to ordinary window glass and to quartz.

It is important to know that quality of transmission alone is not sufficient. The quantitative transmission in the vital zone must also be known. Ordinary window glass taken from my front door gave no radiation less than 3100 A.u. A sample of plain vitaglass, 2 mm thick

FIG. 9—Air cooled mercury vapor arc in quartz therapeutic model—a. at ignition, exposure time according to energy at 20-30 volts, b. 10 minutes after ignition, exposure time according to energy at 75 volts.

FIG. 14

FIG. 15—Law of inverse squares. Illumination of a surface varies inversely as the square of the distance from the source to the surface.

gave 48.7 per cent transmission for the zone from 3100 to 2925 Å. A piece of clear Correx, 4 mm thick, gave 69.6 per cent transmission in the same zone. In these tests the source of the effective vital ultraviolet was a direct current, 3.5 ampere scientific (upright) mercury vapor arc in quartz.

I pass rapidly in review the graphs for the emission of the incandescent bulb. It makes little difference if this be for a 1000 watt or 1500 watt bulb, whether a carbon or tungsten filament. The incandescent bulb gives about one to two per cent of the intravital ultraviolet (it all must pass through the glass enveloping bulb), four per cent of visible light, and 94 per cent of heat. Of this heat the bulb, if of clear glass, absorbs practically all of the

lengths. The energy of such wave lengths emitted by the source studied could then be actually measured by means of a thermopile and a galvanometer. The ergs of energy per square millimeter of area per second of time at 40 inches distance from the source were checked against a registered bulb of the United States Bureau of Standards.

We now have available for the first time data to compare with clinical findings. A gas filled tungsten filament bulb of glass, whether blue, clear, or frosted, whether 10 watt or 1500 watt does not give radiation protection against rickets, and does not sunburn or suntan, no matter how long the exposure may be. We now know how to compare the sources given with the clinical results obtained from their

## CHART TWO

radiation of wave lengths longer than 3000 millimicrons, and it completely absorbs all the radiation of wave lengths longer than 4,500 millimicrons. The low temperature radiation from the heated bulb (some 11 per cent of the total) cannot penetrate deeply into the skin. The spectral component radiation extending from 600 millimicrons in the red to 1400 millimicrons, amounting to about 30 per cent of the total, can (according to W. W. Coblentz) penetrate deeply into the skin.

The next illustration is that of the comparative emission of the Globar material used in the so-called infra red emanators.

The law of the inverse squares actually applies to a theoretical point source. The principle involved is that energy striking the part is inversely according to the square of the distance from the source. Doubling the distance from the source, reduces the unit of intensity per area of the energy to one quarter.

I come now to a contribution to the subject of phototherapy with ultraviolet. I owe this to the splendid cooperation of William T. Anderson, Jr., Ph.D., by which I have been enabled to study at first hand the quantitative emanation of the sources of such radiation used in my practice.

These sources of ultraviolet were measured by means of a series of quartz prisms and slits arranged to permit preselection of wave

use. We now know how much radiation in the ultraviolet is effective radiation in the vital ultraviolet zone, and how much radiation in the ultraviolet has no effective reactions recognizable to us.

With further study of the common sources of radiation we will be prepared to give some quantitative estimation of dosage which to date has been purely empiric. We will seek also to compare ultraviolet dosage with erythema production.

My contention is that the dermatologist, and all physicians using ultraviolet must learn from the manufacturer of the apparatus utilized HOW MUCH of the radiation of ultraviolet emanators is VITAL ultraviolet. My contention is that we must not be misled by division into the coarse bands of infra red, visible, and ultraviolet, nor by further division into near, middle, and far ultraviolet. We must know more than that. We now have the opportunity of asking what share of the emission of the apparatus at operating conditions lies in the zone from 3100 to 2900 Angstrom units. We must then learn by experience the factors of time and distance. With these four factors, quality, quantity, time, and distance, we can reproduce effects and advance the field of phototherapy within the limits of the variant factor of the patient.

## THE WORKMEN'S COMPENSATION LAW IN ITS RELATION TO THE PHYSICIAN\*

By JAMES A. HAMILTON, Ph D,  
The Industrial Commissioner, State of New York.

WHEN an employee covered by the Workmen's Compensation Law receives an injury "arising out of and in the course of employment" or develops "any such disease or infection as may naturally and unavoidably result therefrom," it is the duty of his employer under Section 13 of the Workmen's Compensation Law to promptly provide for him "such medical, surgical or other attendance or treatment, nurse and hospital service, medicine, crutches and apparatus for such period as the nature of the injury or the process of recovery may require"

It will be noted from the preceding quotation from the law that the duty of the employer to provide medical treatment for an injured employee is absolute, and that the length, kind and quality of such treatment is limited only by the requirement that medical service be rendered "for such period as the nature of the injury or the process of recovery may require"

Illustrative of the fact that no time limit is placed upon necessary medical services is a report of hearing in September in which claim was made for such service to one patient for a period of six years. Originally, the law restricted such treatment to 60 days but since 1922 there has been no limit save such "as the nature of the injury or the process of recovery may require" The newspaper report is as follows

"Dr Sengstacken presented a bill for caring for Joseph Miller, who died last February after having been bedridden for nearly six years. Miller was injured in August, 1921, while employed on the Gormley brick yard. He was working on a brick shed with one foot across a cross beam when he fell

"According to Dr Sengstacken, the man's right side was paralyzed, he suffered abrasions on the head and his right shoulder was hurt. Miller, he said, never regained the use of his right arm but a marked improvement developed as far as his legs were concerned

"Dr Sengstacken attended the man until the time of his death, which was caused chiefly by apoplexy, but contributory factors resulted from his accident, he said. The case was adjourned to New York City"

It is the duty of the employer to provide medical services at his own expense. He may insure payment of such expenses in his compensation policy, or he may assume the burden himself. But in either case, the law holds the employer responsible

To physicians it is of importance to note this power of choice by the employer. It does not rest in the insurance carrier. When a physician has been selected by the employer, and has begun treatment of a case, the insurance carrier has no right to take away, or "lift" such case and transfer it to another physician

Furthermore, if the physician selected by the employer deems it advisable and necessary to call a consultant physician, or specialist on the case, he has power to authorize their services. Each such consultant, or specialist, so brought into the case must file the prescribed form C4 and show authorization for the services he has rendered

Section 13 of the compensation law gives the injured employee himself the right to secure medical treatment at the expense of the employer "if the employer fails to provide the same, after request by the injured employee," or if the employer or his representative, having knowledge of the injury "shall have neglected to provide" medical service. In such cases, either of two situations may arise. The employee may himself make payment to the physician. If so, the employee may then come before the Board and ask reimbursement in the form of an award against the employer for the amount of the bill. The Board, if it finds the bill reasonable, may make such award. If the employee does not pay the medical bill, the physician may appear before the Board, show that he rendered service at the request of the employee, and secure an award for the sum. In both of these situations, the Board, in determining the fees, is governed by Section 13 which requires that they "shall be limited to such charges as prevail in the same community for similar treatment of injured persons of a like standard of living"

At all times, the Board has had power to pass upon the adequacy of medical treatment. If the Board finds, for example, that an injury under treatment is not responding properly and that such delay in healing is due to improper treatment, another physician, or other form of treatment, may be suggested. Where the employer furnishes the medical service, there has usually existed a direct, contractual relation between the employer and the physician and the Board has not entered into the matter of fees. Since the enactment of Chapter 553, Laws of 1927, effective on July 1, the Board has been given power to regulate fees for medical treatment and services "whether furnished by the employer or otherwise"

\* Read before the First District Branch, Bronx, New York, October 20, 1927

The enormous number of accidents, approximately 500,000 in number, reported annually to the Department of Labor, necessarily requires that an orderly method of procedure be adopted and strictly followed so that the cases may be disposed of as expeditiously as possible. Rules have been adopted, and forms have been prescribed, for this purpose. Such regulations are applicable to all parties having anything to do with the case, including employer, employee, insurance carrier, and by no means exempting physicians, hospitals and all other persons and organizations who are in any way related to the medical handling of the case.

The medical aspects of the Workmen's Compensation Law have from the enactment of the statute been the occasion of misunderstanding. Much of this has been due to a lack of understanding on the part of physicians, employers and insurance carriers as to their duties under the law. Time, and some amendments to the law, have brought about a large measure of correction and there exists today a much better understanding on the part of all concerned as to the medical aspects of the law. I trust that such growth of knowledge and of mutual understanding will continue until the last vestige of misunderstanding disappears.

Some of the duties of a physician who treats a compensation case may be here set down. Of prime importance is the necessity for filling out and forwarding to the Department of Labor what is known as Form C4. This is the report made by the physician as to first treatment rendered to the injured worker. Most of you are, perhaps, familiar with this form. Each item on it should be filled out as the information called for may be needed in later administration of the case by the Department of Labor.

From the standpoint of protecting the physician's compensation, this Form C4 must be filed within 20 days after the first treatment. This definite time limit, specified in Section 13 of the law, has been upheld by the courts and cited by them as the basis of refusing payment of medical bills. As an illustration of the effect of failure to file the C4 within 20 days, the following newspaper account of a compensation hearing, held in September of this year, may be given.

"In the cases of Dr. Kline and Dr. Leitner, the Utica Mutual Company refused to pay bills for their care of John DeGroat following a long period of illness as the result of an infection while employed at the shoe factory of Burger and David in Nyack.

"DeGroat first went to Dr. Kline for treatment in December, 1924, and was attended by the physician for several months. Dr. Kline's bill amounts to \$284 and, while on a vacation,

he turned his patient over to Dr. Leitner, who performed two operations. The latter's bill is \$343.

"The bills of the two physicians have remained unpaid for fifteen months, and on the stand Dr. Leitner said to a representative of the carrier, 'I'll turn the money over to the hospital if you'll pay the bill.' The company opposed payment of the bills on technical grounds, contending that Dr. Kline had not presented a proper blank to his company and that it had been filed ten days later than is provided under the State Law."

The opposition to payment of these bills, it will be noticed, was based upon technical grounds of failure to file reports within the time limit set by law. Under the law, and court rulings, that is a valid defense against payment of the bills, whatever may be thought as to its propriety.

Another point to bear in mind in connection with Form C4 is that a copy must be furnished to the employer as well as to the Department of Labor. In the case just referred to, the carrier alleged that this form had not been furnished to their office.

In filling out the C4, the physician should likewise be careful to swear to the affidavit provided at the end. This renders the report *prima facie* evidence and often renders it unnecessary for the physician to attend the hearing as a witness. Trouble in making this affidavit may be avoided by having the office stenographer, or nurse, take out notary papers, or perhaps the wife of the physician. It is also advisable to keep an office record of the date on which the C4 is mailed to the Department and to the carrier. Mails do at times go astray, and a definite record that such form was actually mailed on a given date may be serviceable in establishing the fact that the report was mailed on time.

Some of you may wonder why so much stress is here placed upon the necessity of filing the C4 within 20 days in view of the fact that by Chapter 553, Laws of 1927, the Industrial Board was authorized to excuse the failure to give such notice within 20 days when found "to be in the interest of justice to do so." The reason is that the mandatory requirement of filing within 20 days still remains in the law, and that delay will be avoided by filing within that time limit.

One item in the C4 should be carefully observed. This question, number 9, reads as follows: "Who engaged your services?" A physician in order to receive payment for his services must secure proper authorization from the responsible party. No injured employee should be refused treatment, but it is incumbent upon the physician that he discover from the patient the name of his employer, and

promptly notify the employer of such treatment and secure authorization for the medical service rendered. Without such authorization, the employer, or his insurance carrier, may refuse payment alleging this lack of proper authorization. Many such instances have actually occurred. It may occur that the employer has already offered the services of another physician. In such case, the employee will have no legal right to demand payment by employer of a different physician.

What is said of the C4 applies also to the Form C27 known as the "attending physician's supplemental report." While the 20-day time limit does not apply, it is necessary in order to protect the injured employee's rights that it be properly filled out and duly filed. Here again the affidavit at the end constitutes *prima facie* evidence and may save the physician a visit to the hearing as a witness.

Even in these days of ubiquitous typewriters, there is still some writing done by hand. The much smaller amount of such writing has, however, almost placed chirography among the lost arts of the ancients. While not especially singling out physicians as shining examples of poor handwriting, yet, judging from the reports which have come under my observation, I should say that some improvement is possible. Technical terms which roll trippingly from the tongue of the surgeon or practitioner, are puzzling even in clear print to the laymen who, for the most part, are engaged in administration of the Compensation Law. And when these terms are reduced to writing, there is even greater need of clearness if they are to be understood.

I should like to throw out a challenge to the medical profession with regard to the great field of industrial medicine and surgery. Broadly speaking, it may be said that the enactment of the Workmen's Compensation Laws, now almost universal in the United States, has opened up these new fields in medicine. This is especially true as to occupational diseases. Not that the field was wholly undeveloped hitherto, but compensation laws gave it such an impetus that medical colleges, hospitals, nurses, and the great army of practitioners and surgeons are in duty bound to give it new and especial attention. The compensation laws constitute one of the greatest practical steps ever undertaken in our society towards industrial justice for the rank and file of working people. It is not charity, but elemental justice to compensate industrial workers for accidental injuries received in the course of employment. To achieve this end, it is an obligation resting upon all concerned, physicians no less than others, to seek the clearest light available, and to see that the spirit and purpose of this beneficent statute are fulfilled.

May I close with reference to the ancient and noble oath of Hippocrates, which every one of you subscribe to at your entrance into the honorable profession of healing, and call upon you, not only to render your services in every case of need, but also to protect the injured employee in rights to which he is entitled by due observance of the procedure necessary to secure compensation for himself. By so doing, you protect not only him but yourself as well.

## UNUSUAL CASE OF DIABETIC ACIDOSIS WITHOUT KETONURIA OR KETONEMIA

By ABRAHAM RUDY, M D, NEW YORK, N Y, and CHARLES M LEVIN, M D,  
RICHMOND HILL, L I, N Y

**W**E are presenting this case because 1 Diabetes may be discovered for the first time in old people and can be dangerous, contrary to common belief that the disease is mild in old age. 2 This is another case of diabetic acidosis without the presence of acetone bodies in the urine and blood.

The history briefly is as follows:

E C, female, white, widow, English, 72 years of age. Family history is negative. No diabetes or kidney diseases. Previous history. Does not remember any childhood diseases. Bore 11 children, 6 now living, no miscarriages. Otherwise previous medical and surgical history is negative.

**Present Illness**—On October 10, 1926, patient awoke with slight headache, a dull depressed feeling and without any desire for food. She took

nothing but milk. She tried to get about but felt peculiarly weak and went to bed. She became progressively worse and although she was nauseated and retained nothing but milk which she continuously sipped, she sought medical advice in the evening of October 14th only because of great shortness of breath and "gas around the heart." When seen for the first time at her home that evening the physical examination revealed a short very obese woman propped on pillows with very marked dyspnoea, appearing acutely ill, skin and mucous membranes pale and very dry. Temperature 96.4. Pulse thready and feeble. Mouth was dry and tongue heavily coated, few teeth in poor condition and breath distinctly sour. **Lungs**. A few fine moist rales were found at the bases of both lungs, otherwise

clear *Heart* was weak, sounds of poor quality, action very irregular, ranging from 150-170 and at times could not be counted. B P readings low and unsatisfactory. *Abdomen* quite distended, not tender. Visceral outlines could not be determined because of distention and obese character. *Extremities* cold and somewhat edematous at the ankles.

*Urinalysis* Pale, clear, spec gr 1040, heavy albumen heavy sugar, no acetone or diacetic acid. Microscopically, some pus cells, no red cells or casts. *Blood chemistry* Plasma sugar 750 mgms per 100 c.c. (Benedict), urea, 76 mgms per 100 c.c., no plasma acetone (Wishart-Rothera test), carbon dioxide combining power was 37.

In spite of the absence of acetone bodies in the urine and blood a diagnosis of impending coma was made. The administration of insulin and carbohydrates (in the form of orange juice) was started at once. A trained dietitian was immediately called on the case. The patient was put on stimulants. Fluids were forced hourly with three small doses of bicarbonate of soda and enemata given for bowel relief. The next morning the patient felt much easier and there was a marked improvement in her breathing. A blood sugar determination at 8 A. M. showed 500 mgms per 100 c.c., the urea was 82 mgms per 100 c.c., and there was no acetone in blood and urine. Insulin administration was guided by repeated urine tests. Only after a total of 210 units of insulin with 145 gms of carbohydrates in 20 hours did the urine become sugar free. The patient was closely watched for hypoglycemia. At 9 30 P. M., October 15th, she began to show signs of a low blood sugar and a blood test done at this time showed 85 mgms of sugar in 100 c.c. She received 10 gms of CHO and no insulin was given that night. Urine tests were done every 2 hours. On October 16th her condition had improved remarkably. Respirations were 24. Temperature 96.8. Heart still irregular but of better quality, pulse 110, irregular and somewhat thready. Her urine was negative for sugar and acetone. She was placed on a program of protein 30 gms (because of the high urea), carbohydrate 80 gms and low fat with 60 units of insulin in divided doses of 20 units each t.i.d. She was kept sugar free for 10 days on this diet and we were able to reduce her insulin from 60 units daily to 30, guided all the time by slight hypoglycemic symptoms. A blood test done on October 28th before supper and insulin showed a plasma sugar of 200 mgms per 100 c.c. and a blood urea of 32 mgms per 100 c.c. A diet change only in the protein was made from 30 gms to 60 gms daily. Two days later she began to show again sugar in her urine. There was no apparent cause for this because of strict observation. Her insulin requirement gradually rose to 60 units daily and within 3 days an acute inflammation in the region of the right parotid gland

developed. With hot fomentations, insulin and strict diet this condition subsided within a week without surgical interference. Following this her insulin dosage dropped back to 30 units daily. She was getting along nicely until December 16th when she started to feel sick again without any definite complaint. We were called on December 18th when she was seized with an attack very similar to the first but more acute in onset. There was a very marked dyspnoea of the Kussmaul type. She appeared terrified and begged not to let her die. Her face was very pale and haggard, with fine perspiration. Her heart action was irregular and rapid. In spite of the thought of a recurring acidosis (later she confessed that she broke her diet for a few days) a hypoglycemia was considered and therefore orange juice was administered and adrenalin hypodermically given right after a blood sample for a test was drawn. Further stimulants for the heart were ordered. The plasma sugar was 441 mgms per 100 c.c. at 11 A. M. in spite of her usual morning insulin and a breakfast at 9 A. M. consisting only of orange juice (she omitted the rest of her breakfast because of nausea). The urine showed only a trace of sugar. There was no acetone bodies present in the urine and blood. She was given 30 units of insulin in addition to her regular dose. The next morning the blood sugar was 220 mgms and the urea 64 mgms per 100 c.c. The urine was sugar and acetone free. Within a few days she was regulated back on her old program. Since that time she is taking care of her daily duties on a diet 60 protein, 80 carbohydrates and 1000 calories and her insulin, when last seen in February, 1927, had dropped to 10 units.

**DISCUSSION**—This is a very instructive case of diabetic acidosis from which several important conclusions may be deduced. It proves the importance of a routine urinalysis on the acute case seen at home by the general practitioner as well as he does with his chronic cases. A positive sugar certainly does not prove that diabetes was the cause of this condition, at the same time the negative acetone did not exclude an acidosis in this case. We learn here that the combination of all the symptoms together with the laboratory findings gives the diagnosis. If not for the sugar findings and characteristic symptoms such as marked dyspnoea, polyuria, polydipsia and excessive dryness this case might be the picture of an acute myocardial insufficiency with auricular fibrillation or one of the so-called "acute indigestions." A blood chemistry is always of great importance in this type of case. The low  $\text{CO}_2$  combining power despite negative acetone and the very high blood sugar means acidosis. Another proof is the marked improvement of the dyspnoea within 12 hours under insulin administration. There was not enough digitalis and caffeine given to explain the quick effect. The insulin dosage of 210 units in 21 hours and the fact that she

promptly notify the employer of such treatment and secure authorization for the medical service rendered. Without such authorization, the employer, or his insurance carrier, may refuse payment alleging this lack of proper authorization. Many such instances have actually occurred. It may occur that the employer has already offered the services of another physician. In such case, the employee will have no legal right to demand payment by employer of a different physician.

What is said of the C4 applies also to the Form C27 known as the "attending physician's supplemental report." While the 20-day time limit does not apply, it is necessary in order to protect the injured employee's rights that it be properly filled out and duly filed. Here again the affidavit at the end constitutes *prima facie* evidence and may save the physician a visit to the hearing as a witness.

Even in these days of ubiquitous typewriters, there is still some writing done by hand. The much smaller amount of such writing has, however, almost placed chirography among the lost arts of the ancients. While not especially singling out physicians as shining examples of poor handwriting, yet, judging from the reports which have come under my observation, I should say that some improvement is possible. Technical terms which roll trippingly from the tongue of the surgeon or practitioner, are puzzling even in clear print to the laymen who, for the most part, are engaged in administration of the Compensation Law. And when these terms are reduced to writing, there is even greater need of clearness if they are to be understood.

I should like to throw out a challenge to the medical profession with regard to the great field of industrial medicine and surgery. Broadly speaking, it may be said that the enactment of the Workmen's Compensation Laws, now almost universal in the United States, has opened up these new fields in medicine. This is especially true as to occupational diseases. Not that the field was wholly undeveloped hitherto, but compensation laws gave it such an impetus that medical colleges, hospitals, nurses, and the great army of practitioners and surgeons are in duty bound to give it new and especial attention. ## UNUSUAL CASE OF DIABETIC ACIDOSIS WITHOUT KETONURIA OR KETONEMIA

By ABRAHAM RUDY, M.D., NEW YORK, N. Y., and CHARLES M. LEVIN, M.D., RICHMOND HILL, L. I., N. Y.

**W**E are presenting this case because 1 Diabetes may be discovered for the first time in old people and can be dangerous, contrary to common belief that the disease is mild in old age. 2 This is another case of diabetic acidosis without the presence of acetone bodies in the urine and blood.

The history briefly is as follows:

**E. C.**, female, white, widow, English, 72 years of age. Family history is negative. No diabetes or kidney diseases. Previous history. Does not remember any childhood diseases. Bore 11 children, 6 now living, no miscarriages. Otherwise previous medical and surgical history is negative.

**Present Illness.**—On October 10, 1926, patient awoke with slight headache, a dull depressed feeling and without any desire for food. She took

nothing but milk. She tried to get about but felt peculiarly weak and went to bed. She became progressively worse and although she was nauseated and retained nothing but milk which she continuously sipped, she sought medical advice in the evening of October 14th only because of great shortness of breath and "gas around the heart." When seen for the first time at her home that evening the physical examination revealed a short very obese woman propped on pillows with very marked dyspnoea, appearing acutely ill, skin and mucous membranes pale and very dry. Temperature 96.4. Pulse thready and feeble. Mouth was dry and tongue heavily coated, few teeth in poor condition and breath distinctly sour. **Lungs.** A few fine moist rales were found at the bases of both lungs, otherwise

bodies in the blood were present. A dietitian was put on the case and the usual treatment with CHO and insulin followed.

Cases of this sort should be sent to the proper institutions unless a diabetic consultant is available and a dietitian or a nurse trained in diabetic work can be put on the case for a time. After the acute period is over and proper instructions to members of the family are given as to diet and insulin the subsequent treatment and care may go on uneventfully. We have observed that the ordinary person after the proper instruction and explanation as to the condition and the importance of the dietetic care of the patient can accomplish much more than has ever been supposed.

**Summary**—A case of diabetes mellitus and acidosis discovered for the first time in a woman 72 years of age is presented. The problem of a diabetic acidosis without acetone bodies in the urine and blood is discussed and literature reviewed. A typical diabetic acidosis and its treatment at home are described.

**Methods Used in Making Determinations**—The chemical methods used were the following:

- 1 Sugar in the urine, the qualitative Benedict test.
  - 2 Acetone and aceto-acetic acid in the urine, the qualitative Rothera test (a nitroprusside test).
  - 3 Plasma sugar, the Benedict method.
  - 4 Aceto-acetic acid and acetone in the plasma, the Wishart application of the Rothera test to the plasma.
  - 5 CO<sub>2</sub> combining power of the plasma the Van Slyke method.
  - 6 Quantitative blood urea the Van Slyke and Cullen's modifications of Marshall's Method.
- The results of the qualitative tests for sugar and acetone are reported on an arbitrary scale, as

follows: Negative (O), Trace (T), Very Faint (V F), Faint (F), Moderate (M), Heavy (H).

The Rothera test is the most delicate test for diacetic acid and acetone. It is sensitive to one part of aceto-acetic acid in 20 000, while ferric chlorid reacts only to about one part in 8 000.

## STANDARDIZED TREATMENT IN EARLY SYPHILIS AS A MEANS OF ELIMINATING NEUROSYPHILIS\*

By A. BENSON CANNON, M.D., NEW YORK, N. Y.

THE most discouraging problem that confronts the syphilologist of today, despite modern improved therapy, is the treatment of late neurosyphilis. To deal with the condition adequately, treatment should be started before, or at least during the period when the nervous system becomes involved, which is now generally conceded to be the early secondary stage of the disease. Some observers even believe that there is a rash of all the viscera, and probably of the meninges, accompanying the cutaneous rash. In support of this belief there has occasionally been found an eruption on the

bladder walls during secondary syphilis "Syphilis of Bladder," by E. F. Chocholka, *Zeitschrift f Urol Chir* 1926 vol 21, Part 3 and 4, page 134. Kyrle of Vienna stated that 80 per cent of untreated syphilitics showed some pathology of the spinal fluid between the sixth and ninth month of the infection. Udo J. Wile and John Hinchman Stokes, "Further Studies on the Spinal Fluid with Reference to the Involvement of the Nervous System in Early Syphilis," *J A M A*, vol 64, page 1465-1470, May 1, 1915, find that 73 per cent of early syphilitics showed abnormality of the central nervous system. That this percentage does not hold true throughout the course of the disease

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls May 11 1927.

could not stand more than 30 units daily a few days later on a diet of protein 30 gms, carbohydrates 80 and calories 800 confirms the condition of acidosis. The frequent administration of CHO during the first 24 hours was done with the idea of burning up the acetone bodies or other acids present and preventing severe hypoglycemia which would have been dangerous in her case because of the poor condition of her heart. It is of interest to note that the glucose and insulin in these cases not only improve the acidosis but also act as a heart stimulant. The high urea which appeared in this case is quite common in diabetic acidosis.

Despite the general opinion that diabetes in elderly people is harmless there are exceptions, for it is readily seen that acidosis develops in an old person to whom diabetes was unknown. This case was treated at home under constant observation with a dietitian in attendance for a full week.

Diabetic acidosis without ketonuria already has been seen in 1883 by E. Stadelman<sup>1</sup>, in 1884 by von Frerichs<sup>2</sup> and later by Lepine<sup>3</sup>, Revillet<sup>4</sup>, McCaskey<sup>5</sup> and others. Rosenbloom<sup>6</sup> believes that his 3 fatal cases of diabetic acidosis without ketonuria belong to "a type not due to intoxication with acetone bodies and possibly due to intoxication with aminoacids, polypeptides or unknown substances found in the intermediary metabolism. On this basis he explains the inadequacy of the alkaline therapy. In their experimental studies of diabetic acidosis Allen and Wishart<sup>7</sup> came to the conclusion that the acetone bodies in the urine, blood and the plasma CO<sub>2</sub> content are not always parallel. Death may occur with a normal plasma CO<sub>2</sub> and high ketones or low CO<sub>2</sub> and low plasma acetone bodies. They are inclined to believe that a specific intoxication with acetone substances together with an element of true acidosis is the chief known cause of diabetic acidosis. Peters, Bulger and others<sup>8</sup> believe that diabetic coma may be caused in part by acids formed as a result of associated pathologic processes. Appel & Cooper<sup>9</sup> reported very recently 5 cases of clinical diabetic acidosis with a low plasma CO<sub>2</sub> but with a negative ferric chlorid reaction in the urine at some time in the course of the disease. There was, however, in these cases at times a high ketonemia. They give a complete review of the literature concerning this subject. Argy<sup>10</sup> and Feinblatt<sup>11</sup> each reported a case in which they found a large amount of acetone bodies in the spinal fluid without ketonuria and in one case without ketonemia. It would be of great interest to examine the spinal fluid of a large number of coma cases (at least fatal cases) for acetone bodies.

Starr and Fitz<sup>12</sup> studied the excretion of organic acids in the urine of a large number of diabetics. They divide the diabetic acidosis in 2 groups. In the first group the acetone bodies alone appear responsible for the acidosis. The

lowered plasma carbonate content corresponds to the molecular concentration of the acetone bodies. These cases respond very well to insulin because of a better oxidation of the carbohydrates in the blood. In the second group they place those cases where other acids than the acetone bodies are the cause of acidosis. In this latter group a larger amount of unidentified organic acids is excreted through the urine. The low CO<sub>2</sub> combining power of the blood does not correspond to the molecular concentration of the acetone bodies in the blood. These cases, they claim, respond more to alkali therapy than to insulin. For this reason they believe that all diabetic acidosis should be treated with insulin and alkali combined. A. R. J. Dungan,<sup>13</sup> who continued the work of Allen and Wishart, in administration of acetone bodies in order to determine their relation to the symptoms of diabetic coma came to the following conclusion: "It is highly unlikely that either of these acids can directly cause the symptoms of at least the majority of cases of diabetic coma. The possibility merits serious consideration that an intoxication of the same nature as that obtained by the administration of aceto-acetic acid in dogs, produced by the overloading with material of the weakened mechanism for the oxidation of aceto-acetic and hydroxybutyric acids, plays an important or the predominant part in the production of diabetic coma." Our case, as well as all the other cases of diabetic acidosis without ketonuria or ketonemia and also the experimental work on the acetone bodies, point to the conclusion that the acetone bodies are not always the *direct* or the *only* cause of diabetic acidosis resp. coma. Thus the problem of diabetic acidosis must still be considered unsolved.

In contrast to this unusual case we feel justified in mentioning briefly a routine case of diabetic acidosis treated at the same time at home.

Mrs. A. F., 62, widow. *Previous History* Negative up to five years ago when diabetes was discovered. Diet and treatment instituted but patient disregarded all instructions and refused to diet. *Present History* Patient complained of ill feeling on evening of January 30, 1927, and went to bed. She became depressed and nauseated, began to vomit, and was unable to retain anything. Patient summoned a physician who treated her for three days and then recommended removal to hospital for operation for cholelithiasis. When seen for first time, evening of February 2, patient appeared very ill, dry, markedly dyspnoic and vomiting. Heart sounds were good, rate was 130. Lungs negative.

Urine showed heavy sugar and heavy acetone. Glucose was administered intravenously after a blood sample was taken. Insulin subcutaneously followed the glucose. The blood sugar was 536 mgms per 100 c.c., plasma CO<sub>2</sub> combining power was 24, and heavy acetone

bodies in the blood were present. A dietitian was put on the case and the usual treatment with CHO and insulin followed.

Cases of this sort should be sent to the proper institutions unless a diabetic consultant is available and a dietitian or a nurse trained in diabetic work can be put on the case for a time. After the acute period is over and proper instructions to members of the family are given as to diet and insulin the subsequent treatment and care may go on uneventfully. We have observed that the ordinary person after the proper instruction and explanation as to the condition and the importance of the dietetic care of the patient can accomplish much more than has ever been supposed.

**Summary**—A case of diabetes mellitus and acidosis discovered for the first time in a woman 72 years of age is presented. The problem of a diabetic acidosis without acetone bodies in the urine and blood is discussed and literature reviewed. A typical diabetic acidosis and its treatment at home are described.

**Methods Used in Making Determinations**—The chemical methods used were the following:

- 1 Sugar in the urine, the qualitative Benedict test.
  - 2 Acetone and aceto-acetic acid in the urine, the qualitative Rothera test (a nitroprusside test).
  - 3 Plasma sugar, the Benedict method.
  - 4 Aceto-acetic acid and acetone in the plasma, the Wishart application of the Rothera test to the plasma.
  - 5 CO<sub>2</sub> combining power of the plasma the Van Slyke method.
  - 6 Quantitative blood urea the Van Slyke and Cullen's modifications of Marshall's Method.
- The results of the qualitative tests for sugar and acetone are reported on an arbitrary scale, as

follows: Negative (O), Trace (T), Very Faint (V F), Faint (F), Moderate (M), Heavy (H).

The Rothera test is the most delicate test for diacetic acid and acetone. It is sensitive to one part of aceto-acetic acid in 20 000, while ferric chlorid reacts only to about one part in 8 000.

## STANDARDIZED TREATMENT IN EARLY SYPHILIS AS A MEANS OF ELIMINATING NEUROSYPHILIS\*

By A. BENSON CANNON, M.D., NEW YORK, N. Y.

THE most discouraging problem that confronts the syphilologist of today, despite modern improved therapy, is the treatment of late neurosyphilis. To deal with the condition adequately, treatment should be started before, or at least during the period when the nervous system becomes involved, which is now generally conceded to be the early secondary stage of the disease. Some observers even believe that there is a rash of all the viscera, and probably of the meninges, accompanying the cutaneous rash. In support of this belief there has occasionally been found an eruption on the

bladder walls during secondary syphilis "Syphilis of Bladder," by E. F. Chocholka, *Zeitschrift f Urol Chir* 1926 vol. 21, Part 3 and 4, page 134. Kyrle of Vienna stated that 80 per cent of untreated syphilitics showed some pathology of the spinal fluid between the sixth and ninth month of the infection. Udo J. Wile and John Hinchman Stokes, "Further Studies on the Spinal Fluid with Reference to the Involvement of the Nervous System in Early Syphilis," *J A M A*, vol. 64, page 1465-1470, May 1, 1915, find that 73 per cent of early syphilitics showed abnormality of the central nervous system. That this percentage does not hold true throughout the course of the disease

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, May 11, 1927.

is established by the work of J A Fordyce who found an average of 25 per cent of all syphilitics suffering from neurosyphilis, Moore and Kemp, 26 4 per cent and other observers from 30 per cent to 33 per cent. Of our own 208 cases punctured within the first year of the infection, 26 per cent showed positive spinal fluid Wassermanns.

*Meninges probably primarily involved in neurosyphilis*—Kyrle believed that all forms of neurosyphilis, including tabes and paresis, were secondary to a meningitis. On the other hand, Pieters of Hamburg, working with Nonne, showed me the results of an experiment which pointed to the opposite conclusion. He had injected tissue taken from a lesion in the brain of a paretic into the testicles of a rabbit, when the animal was killed six weeks later he found in its brain an infiltration, resembling both macroscopically and microscopically the lesions in the human brain, but without demonstrable spirochetes which had been present so abundantly in the latter. The observation made him believe that some agent in addition to the spirochete was necessary to the production of paresis. He noted further that there was no involvement of the meninges, a process which he believed was secondary to the deeper infection. The experiment would seem to denote that an early syphilitic with parenchymatous involvement was predestined to become a paretic regardless of the treatment he received. However, the serological and clinical evidence of nervous system involvement in early syphilis, and the fact that often many years elapse between the discovery of positive findings and the development of symptoms of paresis or tabes, would indicate that the meningeal infection was primary. It is variously estimated that the incubation period in tabes and paresis is 8 to 15 years or longer, exceptionally, as short as 6 to 8 years.

*Effects of early treatment in neurosyphilis*—It has been my observation during a number of years experience in the study of syphilis that when a patient began a prescribed course of treatment on discovering the initial lesion or the initial lesion with secondaries, and continued this treatment without interruption until 30 arsphenamine and 45 mercury salicylate injections had been given, both his blood and spinal fluid Wassermann were negative at the end of the treatment and remained so. Kyrle made the statement that of the patients who had begun treatment three to nine weeks after the appearance of the initial lesion 100 per cent could be cured by arsphenamine alone. I have frequently examined patients who in the early stages of the infection presented slight clinical evidence of neurosyphilis, such as irregular, unequal and sluggish pupils, hyper-

active deep reflexes and a slightly positive spinal fluid Wasserman, or an increase in cells and globulin, yet at the end of the prescribed treatment showed a spinal fluid entirely negative in all phases. I have done a lumbar puncture on a number of these patients 8 to 10 years later and have found without exception that although there has been no change in the pupillary and deep reflexes, the blood and spinal fluid Wassermanns were negative. I have observed also that patients who show a strongly positive spinal fluid during the secondary stage of the disease are those who have interrupted their treatment, or else are those who have not started antisyphilitic treatment until several months after the primary lesion. Of the 208 cases punctured at the Vanderbilt clinic on an average of 4½ months after infection, these having had either no treatment at all or else inadequate treatment, 50 cases showed a definitely positive spinal fluid Wasserman and other abnormal serological findings. It has been difficult and usually impossible to obtain a negative spinal fluid in these cases even after prolonged and continuous treatment with salvarsan and mercury, only 6 of our cases having been cured by this method. In the others, it was necessary to resort to intraspinal therapy to obtain a negative serology.

*Citation of case*—A typical case was that of a woman aged 35 who was first seen on August 1, 1925, with a history of initial lesion 5 months previous, followed 3 weeks later by marked secondary eruption. She had been given 10 intramuscular injections of sulphar arsphenamine, several weeks after the termination of this treatment she developed intense generalized headaches, marked weakness, followed by an acute mania necessitating a constant attendant. Examination showed unequal, irregular pupils, reacting sluggishly to light, hyperactive deep reflexes with the right knee and ankle jerk slightly more active than the left. The blood serum was 4 plus, the spinal fluid 4 plus to 0.1 cc, 816 cells and a 4 plus globulin. She was treated for 4½ months during which time she received 26 injections of neo-arsphenamine, 28 of mercury salicylate, 10 intraspinal injections of Swift-Ellis serum and potassium iodid by mouth, with a resulting negative blood and spinal fluid findings. The accompanying chart shows the progress of the treatment.

*Treatment employed*—We began in 1916 to give continuous anti-syphilitic treatments with arsphenamine or neo-arsphenamine in combination with mercury salicylate injections. Our routine is as follows: the first six injections of arsphenamine are given every other day, the seventh 3 days later, the eighth 4 days, the ninth 5 days, the tenth 6 days later. The initial dose is 0.3 gm of arsphenamine or 0.45 gms of neo-ars-

Total treatment for 4½ months' period 26 Neo-Arsphenamine, 28 Mercury Salicylate, 10 intraspinal injections of Swift-Ellis serum and Potassium Iodid, by mouth for 6 weeks

phenamine, the amount being gradually increased so that the last 4 injections represent the maximum dose of 0.6 gm. of arsphenamine or 0.9 gm. of neo-arsphenamine or approximately 0.1 gm. of arsphenamine to each 25 pounds of body weight where practicable. The first course of arsphenamine and the first course of mercury salicylate are given simultaneously, the mercury being administered every 5 to 7 days, and in the interval between the completion of arsphenamine and the completion of the mercury we prescribe fifteen to thirty drops (varying with the patient's tolerance) of a saturated solution of potassium iodid by mouth. The second course of 10 injections of arsphenamine or neo-arsphenamine is begun after six weeks, and this time given at weekly intervals. The mercury salicylate is discontinued after the fifteen injections have been given and is not resumed until the completion of the arsphenamine. The third courses of arsphenamine and mercury salicylate are a repetition of the second course. We advise a Wassermann test before and after each course of treatment. If the spinal fluid is positive we repeat the test at six weeks intervals thereafter, the results to be used as a guide in treatment.

*Results in treatment of 150 cases*—While experience has taught us that some cases are undoubtedly cured after one course of treatment as evidenced by repeatedly negative Wassermans and occasionally by a reinfection, we feel that the majority of patients require much longer treatment. We make it a rule to continue at least ten injections of salvarsan and 16 injections of mercury after the Wassermann has become entirely negative. Of 150 cases of primary and early secondary syphilis with a positive blood Wassermann, where treatment was begun within 3 months of the infection and adhered to as prescribed above, the blood Wassermann and spinal fluid

findings have been negative at the termination of the treatment, and in all instances so far as we have been able to observe, has remained so, in some cases up to nine years. We have no record of a case of tertiary syphilis with absence of neurological symptoms and a negative spinal fluid having become positive. Kyrle considered that if the spinal fluid of a syphilitic was negative after he had had the disease three years that it remained so, and usually the disease became fixed after the 4th to the 6th month of infection.

*Conclusions*—We believe that the prevention of neurosyphilis in the primary stage and cure of early neurosyphilis depend on prompt diagnosis by darkfield demonstration of spirochete from the initial lesion, the recognition of clinical symptoms in secondary syphilis and the interpretation of the Wassermann reaction, the established diagnosis to be followed by definite and uninterrupted courses of anti-syphilitic treatment. Once the spinal fluid findings become fixed, as manifested by a moderately to strongly positive Wassermann reaction, increased cell count and a positive globulin test and gold reaction, they usually become negative only following intraspinal treatment. In some cases 3 or 4 intraspinal injections are sufficient to obtain a negative spinal fluid.

Although all cases have to be considered as separate problems, some patients requiring more medication than others, it is far better to over-treat a few than to run the risk of inadequately treating others. Therefore, as a minimum standard treatment, we urge at least 30 injections of arsphenamine, or its equivalent in neo-arsphenamine, and 45 injections of mercury salicylate given as described over a period of nine or ten months, to safeguard every early syphilitic against the dread results of nervous system infection.

is established by the work of J A Fordyce who found an average of 25 per cent of all syphilitics suffering from neurosyphilis, Moore and Kemp, 26.4 per cent and other observers from 30 per cent to 33 per cent. Of our own 208 cases punctured within the first year of the infection, 26 per cent showed positive spinal fluid Wassermanns.

*Meninges probably primarily involved in neurosyphilis*—Kyrle believed that all forms of neurosyphilis, including tabes and paresis, were secondary to a meningitis. On the other hand, Pieters of Hamburg, working with Nonne, showed me the results of an experiment which pointed to the opposite conclusion. He had injected tissue taken from a lesion in the brain of a paretic into the testicles of a rabbit, when the animal was killed six weeks later he found in its brain an infiltration, resembling both macroscopically and microscopically the lesions in the human brain, but without demonstrable spirochetes which had been present so abundantly in the latter. The observation made him believe that some agent in addition to the spirochete was necessary to the production of paresis. He noted further that there was no involvement of the meninges, a process which he believed was secondary to the deeper infection. The experiment would seem to denote that an early syphilitic with parenchymatous involvement was predestined to become a paretic regardless of the treatment he received. ## SOME RELATIONS OF MEDICINE TO INDUSTRY\*

By C-E A. WINSLOW, Ph D, NEW HAVEN, CONN

IT was about a hundred years ago (in 1822) that Professor C Turner Thackrah published his little book on "the Effects of the Principal Arts, Trades and Professions and of Civic States and Habits of Living on Health and Longevity"—the first exhaustive treatise on this subject in the English language. In the first flush of the great industrial revolution he outlined his problem in the following sentences which may well serve as our text this morning.

"If we look immediately at home, we observe the wonders which science and art have affected. We see large buildings, manufactures of almost every kind, and substances so changed, reformed, and combined, that nature could scarcely know her own productions. We admire the inventions of science, alike in their minuteness and their size, their accuracy, and their extent of operation. We see wool converted into cloth, in establishments so numerous and extensive as almost to supply the civilized world, we see the slight blue-flowered product of the field, formed, in the same mill, into the thread which passes through the eye of the needle, and into the canvass which bears our ships to every region of the globe, we see rough and massive minerals drawn from the bowels of the earth, converted on the one hand, into instruments which surpass in power the united strength of the largest animals, and on the other, formed into the finest and most delicate pieces of mechanism.

"These, and works like these, are assuredly wonderful. But while we admire, let us examine. What are the effects of these surprising works—effects, I mean physical and moral? I say nothing of the wealth they produce or have produced, for wealth is good or evil according to its application. I refer to the health of fifty thousand persons, who spend their lives in the manufactories of Leeds and its neighborhood, or in allied and dependent occupations. I ask, if these fifty thousand persons enjoy that vigor of body which is ever a direct good and without which all other advantages are comparatively worthless? I ask, if the duration of life is as great here as in the agricultural districts?"

It is truly extraordinary to see how fully Professor Thackrah outlined the problems of industrial hygiene as we know them at the present day. Among the industrial poisons he describes lead palsy among printers, the hatters' shakes due to mercury, the diseases of painters, lead colic in the pottery trade (in connection with which he advocates the employment of leadless glazes), brass founders' ague

and the like. He discusses silicosis in a classical passage to which I shall return in a later paragraph. He alludes to industrial dermatoses, to the bakers' itch and to cancer among chimneysweeps. He was perhaps the first observer systematically to apply physiological tests as a routine procedure in industrial hygiene, giving reports of the capacity of the lungs as determined by forced expiration into an inverted graduated glass jar. He knew, not only what was dangerous but what was not, for he shows that the odors of decomposing organic matter among tanners and slaughterhouse workers exerted no prejudicial effect. He recognized the supreme importance of alcoholism as a health hazard and he gave the soundest advice in regard to many problems of personal hygiene.

During the century which has passed since the appearance of this little book the progress which has been made is remarkable and significant. We can report with pride and satisfaction that the dangers incident to industrialization have been in large measure overcome and that the average duration of life in many factory communities is today even greater than it is in agricultural districts. In the field of industrial accident prevention in particular the accomplishments of the past two decades have been truly remarkable. The passage of the workmen's compensation acts, which spread so rapidly from state to state between 1909 and 1913, when 23 different states enacted laws of this type, has perhaps been the major factor in such progress. These acts not only placed the burden of non-preventable industrial injury where it belongs, upon the industry itself, but proved the most powerful stimulus to the prevention of those accidents which are preventable by bringing out clearly the cost to the industry of a neglect of due precautions. In 1911 the National Safety Council was organized and has served in increasing degree as a center for the coordination of effort toward this important end. As a result there are numerous industries in which we find that the number of days of absence due to industrial accidents has been reduced to a half or a third of what it was ten years ago. These achievements are now clearly reflected even in the gross death rates of the Federal census. The death rate for all accidental causes was 84 per 100,000 in 1910, and but 79 in 1920, in spite of the fact that automobile accident rates were included in the group and had increased by about eight points during that period. The net difference in the accidental death rate between 1910 and 1920 amounts to a saving of 15,000 lives per year and that figure has been added to year by year

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls N. Y. May 11, 1927.

with the advance of this movement. In the field of industrial poisoning we are again making substantial progress, although the advance is probably not so great as in connection with the simpler and more obvious accident hazard, and is much harder to measure in definite statistical terms. The subtle effects of lead poisoning are still manifest among smelters of lead ores, in the manufacture and handling of white lead and red lead, in the manufacture of storage batteries and in the production of china and earthenware and in a great variety of other industries, above all among painters. Studies made in the United States show that in certain branches of these industries, one out of ten or one out of five of the workers employed may be found on careful examination to show evidence of incipient lead poisoning and these rates are still far in excess of those which obtain in countries like England where the processes have for a long time been carefully supervised and controlled. In English potteries for example only about 1 per cent of the employees suffer from lead poisoning as against 10 per cent shown by the findings of Dr Alice Hamilton in 1911. The remarkable studies carried on by the Harvard School of Industrial Hygiene and published last year by Dr J. C. Aub and his colleagues under the title "Lead Poisoning" (Medicine Monographs, vol. vii) is a contribution of the first importance to the pathology of this disease and opens the way to a rational and satisfactory treatment on the basis of the liberation of stored lead through the control of the acidity of the blood. In the field of prevention, however, there remains much to be accomplished.

The problem of benzol poisoning has received increased attention and was last year made the subject of an exhaustive report by a special committee of the National Safety Council which brought out the fact that more than one-fourth of a group of workers exposed to the fumes of this substance showed clear evidence of early benzol poisoning. The rapidly developing process of spray coating is now being studied by a similar committee of the Council and while the results of that study are still under consideration and can not be made public for the next two or three months it is permissible to point out that the earlier investigation made by the Pennsylvania State Department of Labor and Industry has made it clear that the use of the spray gun may involve the gravest hazards, not only of lead poisoning and benzol poisoning but of silicosis as well.

The control of industrial poison hazards may be accomplished along three general lines. In the first place, where the chief danger lies as is generally the case in the inhalation of toxic dusts and fumes, the hazard may be minimized by various mechanical devices such as the use

of wet instead of dry procedures, the carrying out of dust or fume-producing processes in enclosed chambers, the provision of local exhaust ventilation and the use of masks and respirators. Where reliance is placed upon exhaust ventilation it must be noted that the ventilation provided must be very much greater than is commonly allowed. For example, the Pennsylvania studies in connection with benzol made it clear that an exhaust of approximately 200 linear feet per minute is essential for an adequate protection. In the use of masks and respirators a clear distinction should be drawn between those devices which rely on the filtration principle where the worker must draw in his air supply through layers of cotton or sponge or other filtering material and the type of device which includes a mask or helmet provided with a positive pressure interior air supply. I am personally convinced from my own experience that masks and respirators of the former type are practically valueless for continuous use. If the filtering layer be made of sufficient thickness to prove really effective the device will be so uncomfortable that in practice it will not be worn. If it is sufficiently comfortable to be worn it will invariably be found to be ineffective. These filter masks may be used in emergencies as they were used in the trenches for protection against war gases, but we are living in a fool's paradise if we expect a worker to protect himself by such an apparatus during a continuous period of hours. The second type of mask or respirator with a positive air supply is both effective and practical if properly designed and it is on this type of device alone that we should rely in seeking a mechanical protection against dusts and fumes.

Our second line of defense against the industrial poisons must be sought through a systematic and regular medical examination, aided by the use of the most refined laboratory tests. In the case of two of our major problems, lead poisoning and benzol poisoning, we are fortunate in possessing laboratory criteria in the form of blood tests admirably qualified to reveal the existence of incipient poisoning before its serious results are manifest. I can well remember in this very city during the war visiting a certain plant in company with Dr David Edsall and Dr Gilman Thompson and being told by the plant physician that they very rarely had any cases of lead poisoning. As this seemed surprising, in view of the unsanitary conditions which obtained, we questioned him about the tests which were used and he explained that "The foremen were told to send any men who had lead colic to the office." I have often wondered since whether this physician did not know that there were any other tests for lead poisoning than that which a foreman could apply or whether he thought that it

was his visitors who were unaware of more refined methods of procedure. Today we all recognize I think that no worker should be employed in a trade involving the lead hazard without blood examinations made every three months for the determination of the presence of stippled cells or anemia, while in the case of benzol, the changes in the white cell count will give us tests which should have similar application.

The only complete solution of the industrial hazard problem is of course the elimination of the toxic substance and in many instances intensive study would reveal the possibility of finding some harmless substitute which could well be employed. The Committee on Benzol of the National Safety Council closed its report with a demonstration of the fact that toluol and xylol are far less dangerous than benzol under the conditions of industrial use, and concluded:

"We would therefore urge that the serious attention of manufacturers now using benzol should be given to the possibility of substituting one of these, or other relatively harmless substances wherever the conditions of a given manufacturing process make it possible to do so." In the case of the protection of the painter against lead poisoning the same line of approach seems to offer the only real hope of ultimate success. For outside painting there seem to be serious difficulties in the way of the elimination of lead sulphate but for booth spraying or interior surface painting (except possibly in the case of ship painting) the use of lead paints or of zinc oxide paints containing any major proportion of lead seems wholly unnecessary. The British departmental committee which studied this question and reported last year came out squarely for the important principles that all paints containing lead should be clearly marked as such and that lead paints should not be applied in the form of spray in the interior painting of buildings.

In addition to industrial accidents and industrial poisoning there is a third major problem affecting the health of the worker—the problem of silicosis. This danger I believe is on the whole perhaps the most significant and far-reaching of the three, and it is today certainly the one which is most generally neglected. Thackrah one hundred years ago said "The affections of the lung and air tube induced by industry are the most urgent of the maladies which result from our employments," and this is true today. He pointed out that the fork-grinders of Sheffield who used a dry grindstone died at the ages of 28 to 32 while the table knife grinders who worked on wet stones survived until between 40 and 50. That the process of wet grinding is by no means necessarily an efficient protection is clearly indicated

however by studies which we have made at an axe factory in Connecticut where the death rate from tuberculosis for a period of twenty years was 1900 per 100,000 among the grinders and polishers (for the most part doing wet grinding on natural sandstone wheels) while it was 160 for the rest of the employees of the same factory. The inhalation of almost any type of dust in large quantities has a profound effect in increasing susceptibility to acute respiratory infections such as bronchitis and pneumonia but when the inhaled dust contains free silica there is in addition a specific and definite increase in the incidence of tuberculosis which is one of the most striking and remarkable factors in the etiology of this disease. The table below presents comparable mortality figures for England and Wales for the ten occupations which in 1910-1912 showed the highest rates. These figures are not in terms of deaths per 100,000 but in the form of arbitrary comparative mortality figures. I have therefore included the comparable figure for all occupied males and the lowest figure for any occupation, that for clergymen, and also the figure for coal miners to compare with that for tin miners below. It will be noted that the tin miners exposed to silica dust show a comparative mortality nearly ten times that for coal miners, exposed to a dust which does not contain silica. It will be noted that of ten occupations, the only ones showing mortality rates over 250, six are occupations exposed to silica dust including all the three in excess of 420. In the other four cases the high death rates are presumably due either to alcoholism or to a process of selection which draws those who are already suffering from tuberculosis into such industries as messenger service and the street trades.

In connection with the problem of respiratory disease I can not refrain from alluding to what is probably the greatest single cause of

\*Exposed to silica dust.

absenteeism, the common cold From the standpoint of production there is probably no single disease which places so heavy a burden upon industry and in the recent investigations which have been made by the New York State Commission on Ventilation and other students of this subject we have at last one practical method of attacking this important problem. We may conclude from these studies that the overheated living room or schoolroom or workroom has a profound and unsuspected affect in increasing the prevalence of these minor respiratory diseases. In the New York studies, carried on with the greatest care during two successive winters on thousands of school children, it appeared that in rooms with an average temperature of 68.5 degrees the amount of absence due to respiratory diseases was increased 18 per cent and the amount of respiratory sickness among pupils in attendance was increased 70 per cent as compared with a group of rooms averaging 66.5 degrees. There is probably no single thing which would have greater effect in the prevention of preventable industrial disease than the control of overheating in the factory.

On the continent of Europe the problems of industrial hygiene have been dealt with for the most part through the method of official governmental action but in this country the major part of what has been accomplished has been brought about through the initiative of far-sighted employers of labor—stimulated it is true in great measure by the indirect influence of the Workmen's Compensation Act. So soon as the financial burden of industrial accidents was brought clearly to the attention of the industrialist there was initiated a two-fold movement, for the employment of safety engineers on the one hand and of industrial physicians on the other. In most instances the physician was first employed primarily for the purpose of providing first aid for compensable accidents, a measure so obvious that it could not escape the attention of the intelligent factory manager. When a medical department was once organized, however, its field of usefulness quickly enlarged and it became evident that it might often be of advantage for the plant physician to render first aid in minor industrial illnesses of a non-compensable character in order to avoid unnecessary lost time and to promote efficiency in production, and a third possibility was opened up when the employer began to realize that the medical examination of applicants for employment might prove of the highest value in facilitating the proper adaptation of the individual to his job. Dr. H. E. Mock in his admirable textbook on "Industrial Medicine and Surgery" has estimated the profits involved in this aspect of industrial medicine alone as follows. In ten major industries with a medical service estimated to cost in the

neighborhood of \$250,000, over 11,000 applicants were rejected on the basis of the examination, which, on the assumption that these men if employed would soon have been forced to drop out and on the conservative estimate of \$35 as representing the cost of hiring and training a new worker, would involve a saving of \$400,000.

At the shoe factory of the Endicott-Johnson Company near Binghamton the concept of industrial medical service has been developed to a degree which is almost staggering in its possibilities. As described in the *Journal of Industrial Hygiene* for 1924, this plant employed 16,000 workers and the firm provided, not only for these workers but for all the members of their families as well, complete medical care for illnesses of every sort and kind. Three medical centers, each including a maternity hospital, were in operation and the staff included twenty-seven full-time physicians, 51 full-time nurses, 3 dentists, 2 pharmacists, with various clerks and assistants. In addition, hospital care and service of specialists was provided by contract with outside institutions and specialists. The total cost of service amounted to \$400,000, \$25 per employee or perhaps \$5 per individual covered. The service was not organized as a philanthropy but because of the conviction of the head of the firm that it pays ample dividends in promoting the efficiency and contentment of the working force. If this view be correct the addition to the annual wage of each worker of the sum of \$25 may certainly prove a sound investment.

We may not be prepared to argue for the general extension of industrial medical service on any such far-reaching lines as these. I do believe, however, that a reasonably adequate system of health supervision for the employees themselves should be an essential part of the organization of every modern industry. No factory owner would dream of operating machine tools or power looms without competent experts in his employ to keep them in working order, and the supervision of the living machines in any factory is even more essential for maximum productivity. I look forward in the future (when the present period of post-war slackness and self-satisfaction has passed) to an extensive development of the work of the industrial physician. I believe, too, that the industrial physician will more and more come to be recognized as something more than a doctor who practices his profession for one or more hours of the day within the walls of a factory. The true industrial physician should not only practice minor surgery and render first aid in factory illness and make physical examinations of prospective employees. He should also be familiar with the industry itself, should take an active part in the control of its poisons and

was his visitors who were unaware of more refined methods of procedure. Today we all recognize I think that no worker should be employed in a trade involving the lead hazard without blood examinations made every three months for the determination of the presence of stippled cells or anemia, while in the case of benzol, the changes in the white cell count will give us tests which should have similar application.

The only complete solution of the industrial hazard problem is of course the elimination of the toxic substance and in many instances intensive study would reveal the possibility of finding some harmless substitute which could well be employed. The Committee on Benzol of the National Safety Council closed its report with a demonstration of the fact that toluol and xylol are far less dangerous than benzol under the conditions of industrial use, and concluded

"We would therefore urge that the serious attention of manufacturers now using benzol should be given to the possibility of substituting one of these, or other relatively harmless substances wherever the conditions of a given manufacturing process make it possible to do so." In the case of the protection of the painter against lead poisoning the same line of approach seems to offer the only real hope of ultimate success. For outside painting there seem to be serious difficulties in the way of the elimination of lead sulphate but for booth spraying or interior surface painting (except possibly in the case of ship painting) the use of lead paints or of zinc oxide paints containing any major proportion of lead seems wholly unnecessary. The British departmental committee which studied this question and reported last year came out squarely for the important principles that all paints containing lead should be clearly marked as such and that lead paints should not be applied in the form of spray in the interior painting of buildings.

In addition to industrial accidents and industrial poisoning there is a third major problem affecting the health of the worker—the problem of silicosis. This danger I believe is on the whole perhaps the most significant and far-reaching of the three, and it is today certainly the one which is most generally neglected. Thackrah one hundred years ago said "The affections of the lung and air tube induced by industry are the most urgent of the maladies which result from our employments," and this is true today. He pointed out that the fork-grinders of Sheffield who used a dry grindstone died at the ages of 28 to 32 while the table knife grinders who worked on wet stones survived until between 40 and 50. That the process of wet grinding is by no means necessarily an efficient protection is clearly indicated

however by studies which we have made at an axe factory in Connecticut where the death rate from tuberculosis for a period of twenty years was 1900 per 100,000 among the grinders and polishers (for the most part doing wet grinding on natural sandstone wheels) while it was 160 for the rest of the employees of the same factory. The inhalation of almost any type of dust in large quantities has a profound effect in increasing susceptibility to acute respiratory infections such as bronchitis and pneumonia but when the inhaled dust contains free silica there is in addition a specific and definite increase in the incidence of tuberculosis which is one of the most striking and remarkable factors in the etiology of this disease. ## RADIUM THERAPY IN CERTAIN SKIN LESIONS\*

By EARL L EATON, MD, BUFFALO, N Y

**T**HERE is no longer any question of the usefulness of radium as a therapeutic agent.

The only points left open for discussion are the proper selection of cases to be treated, and the best methods of application under given conditions. Radium has become as well established in the physician's armamentarium as the obstetric forceps, but like this highly useful implement, it must be applied with intelligence and discretion, for in the hands of the novice or of the overzealous enthusiast, it is capable of doing infinite harm.

My experience with radium has been confined to its use in dermatological work, and that again, has been in large measure, restricted to private practice. Therefore, my material, viewed by the standards of large city clinics, may seem meagre, yet I am so impressed by the value of radium in this field, and the need of greater knowledge both of its applications and limitations, that I am led to hope that a brief account of my experience will not be wholly without interest, and may even add a trifle to the sum total of slowly accumulating data which we have good reason to hope will lead to the assignment of radium to its proper place as an agent in the treatment of skin lesions.

Following the usual practice, I shall divide my cases into benign, pre-cancerous and frankly malignant conditions. In general, it may be said that radium gives so much better cosmetic results than surgery, that upon the face and hands the mere consideration of appearance may lead the patient to urge the use of this element, whether or not the condition is such as to lend itself peculiarly to this therapy. In that type of lesion coming under the general classification of "birth marks"—which make up so large a percentage of benign cases and which with few exceptions are treated solely for cosmetic reasons—radium is especially useful, and even in those few instances where its employment may be contraindicated, the temptation to use it is always very strong.

**Vascular Naevi.**—Following the subdivisions used by MacKee, three clinical types of these "marks" may be considered. *Naevus flammeus* ("port-wine mark"), *naevus vasculosus* ("strawberry mark"), and *cavernous angioma*. These types have been thus postulated by this author. "The elevated types of *naevus vasculosus* yield to radium in the most striking manner. Even the cavernous naevus will disappear under safe therapeutic dosage. It seems paradoxical but the superficial port-wine mark is exceedingly recalcitrant. The types that respond well begin after birth and continue to increase in size for weeks and months. There is a numerical increase in the blood vessels which are dilated, abnormally cellu-

lar, and which continue to develop by budding processes. In other words, a new growth in which the cells are more or less embryonic in type. When irradiated it is probable that mitosis is arrested, new vessels cease to form and finally the poorly differentiated cells composing the vessels fail to be replaced and are absorbed. The troublesome port-wine mark is fully developed at birth, the cells are mature, well differentiated and not very active. It can, perhaps, be likened to *telangiectasia*. To cause an obliterating *endarteritis* in *telangiectasis*, *spider naevus* and *port-wine mark* requires an amount of treatment that may seriously injure normal tissue."

This was written in 1921 but the more recent publications regarding the use of radium in this class of new growths are for the most part, equally enthusiastic. Clark found that the vascular types of naevi are much more responsive to radium than the cellular and pigmented lesions. Strawberry marks he treated by plaque applications of 80 to 90 minutes with a filtration of 1 mm brass and 4 or 5 mm of rubber, taking care to avoid producing much erythema. "A faint level whitening of the skin" was regarded as a satisfactory final result. He also obtained good results on cavernous angioma by using cross-fire applications. When the lesion was upon the cheek, the applicators were placed both inside and outside the mouth, the dose given to the mucous surface being about one-third less than that upon the outside skin.

Of the port-wine marks he speaks more enthusiastically than most of the other writers I have examined. He found radium to be the best curative agent he had ever tried, but admitted that the "end-results are far less proportionately perfect than in the vascular or cavernous type of lesions." In his experience the technique was easier to use in young subjects, though great care was necessary to avoid severe reaction. "It is regularly necessary to stop short of a complete removal of the discoloration, leaving a faint pinkish color, which, however, is apt to disappear considerably with time." Burns found the flat port-wine stain the most difficult in which to get satisfactory cosmetic results. Small marks he was able to remove with quarter-or half-strength applicators, using nothing more than a 1 mm thick aluminum screen. Extensive marks he found more satisfactorily handled by the ultra-violet ray. All other vascular naevi, he decided were more amenable to radium than any other agent he had employed. "The deeper angiomas require considerable gamma radiation to bring about their involution, and, for this type radium in tubes, radium emanation or full strength applicators should be employed, filtering out at least fifty per cent of hard beta rays, either by brass or lead

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N Y, May 11, 1927.

dusts and other hazards and should be a specialist in the complex problem of adapting the individual worker from a physiological and a psychological standpoint to the particular task which he is to perform

In closing let me point out that the control of industrial disease depends, not alone upon the factory physician however competent, but involves the intelligent cooperation of the medical profession as a whole. Until industrial medicine is far more completely organized than is likely for the present to be the case it will often happen that the early symptoms of industrial poisoning or industrial silicosis will come to the attention of the private practitioner with no first hand knowledge of the hazards which are involved. Only in so far as the private physician becomes familiar with the commoner symptoms of industrial disease, and by careful questioning traces them back to their source and correlates them with the occupation of the patient, will progress be insured. The effect of industrial poisons may be manifest in the widest variety of forms, in nausea or vomiting or colic or constipation, or

more obscure disorders of the digestive system, in headache or dizziness or vertigo, muscular incoordination or neurotic symptoms of a complex and puzzling nature, while the affections of the skin due to various poisons or irritant dusts are almost legion. The Medical Society of New York can perform no more useful function than in calling to the attention of its members the significance of symptoms of this kind and in impressing upon them the importance of the most careful inquiry into occupational history in forming a diagnosis and providing for a scheme of treatment.

There is a famous Chinese proverb in the Thousand Gold Remedies that reads as follows: "The high grade doctor serves the nation, the middle grade doctor the individual, and the low grade doctor treats physical ailments." The physician who not only considers his patient as a whole individual rather than a mass of symptoms, but also considers the entire life of the individual in relation to his occupation and his home and the society in which he lives, is indeed the one who serves his nation and who serves mankind.

## DISCUSSION OF DR WINSLOW'S PAPER

By LOUIS I HARRIS, M D

Commissioner of Health, New York City

PROFESSOR WINSLOW has played a leading rôle in directing attention during more than a decade to the conditions in industry that have had a bearing on the health and the lives of workers. I do not wish to enlarge upon the themes that he has discussed in his eloquent, scholarly and comprehensive survey of the subject. I cannot forego the opportunity of venturing to express, on behalf of the medical profession of this State and of those interested in preventive medicine, a sense of our indebtedness to him for challenging the medical profession to give more than passing notice to the importance of rendering more service in research and in preventive practice to eliminate or ameliorate those industrial factors that threaten the workers—the 44,000,000 children, women and men who are employed in industry.

Year by year the number of the physicians who are drawn into industry is growing. It devolves upon them to apply the lessons which research of the type carried on by Professor Winslow and others has shown to have a life-saving value of great importance. It is not enough that doctors should serve to bind up

wounds and apply their curative art to the casualties resulting from the character of the industrial environment or the specific hazards attendant upon certain industries.

Physicians in industry must apply themselves to the prevention of the enormous number of such casualties. These physicians, as well as clinicians, surgeons and laboratory workers in general must contribute more richly to that type of study and research which will develop more potent weapons for the prevention of industrial diseases.

While social medicine is often spoken of as if it were synonymous with the socialization of medicine, I would like to point out that one of the implications of Professor Winslow's paper is, that effective work of the medical profession in the realm of industrial medicine implies a social service of vast proportions not only to the workers, who are spared from sickness, injury or death, but an equally valuable service to those dependent on wage-earners. Such service prevents dependency due to disability or death of the wage-earner and is therefore a service to the community as well.

## RADIUM THERAPY IN CERTAIN SKIN LESIONS\*

By EARL L. EATON, M.D., BUFFALO, N. Y.

THERE is no longer any question of the usefulness of radium as a therapeutic agent. The only points left open for discussion are the proper selection of cases to be treated, and the best methods of application under given conditions. Radium has become as well established in the physician's armamentarium as the obstetric forceps, but like this highly useful implement, it must be applied with intelligence and discretion, for in the hands of the novice or of the overzealous enthusiast, it is capable of doing infinite harm.

My experience with radium has been confined to its use in dermatological work, and that again, has been in large measure, restricted to private practice. Therefore, my material, viewed by the standards of large city clinics, may seem meagre, yet I am so impressed by the value of radium in this field, and the need of greater knowledge both of its applications and limitations, that I am led to hope that a brief account of my experience will not be wholly without interest, and may even add a trifle to the sum total of slowly accumulating data which we have good reason to hope will lead to the assignment of radium to its proper place as an agent in the treatment of skin lesions.

Following the usual practice, I shall divide my cases into benign, pre-cancerous and frankly malignant conditions. In general, it may be said that radium gives so much better cosmetic results than surgery, that upon the face and hands the mere consideration of appearance may lead the patient to urge the use of this element, whether or not the condition is such as to lend itself peculiarly to this therapy. In that type of lesion coming under the general classification of "birth marks"—which make up so large a percentage of benign cases and which with few exceptions are treated solely for cosmetic reasons—radium is especially useful, and even in those few instances where its employment may be contraindicated, the temptation to use it is always very strong.

*Vascular Naevi*.—Following the subdivisions used by MacKee, three clinical types of these "marks" may be considered. Naevus flammeus ("port-wine mark"), naevus vasculosus ("strawberry mark"), and cavernous angioma. These types have been thus postulated by this author. "The elevated types of naevus vasculosus yield to radium in the most striking manner. Even the cavernous naevus will disappear under safe therapeutic dosage. It seems paradoxical but the superficial port-wine mark is exceedingly recalcitrant. The types that respond well begin after birth and continue to increase in size for weeks and months. There is a numerical increase in the blood vessels which are dilated, abnormally cellu-

lar, and which continue to develop by budding processes. In other words, a new growth in which the cells are more or less embryonic in type. When irradiated it is probable that mitosis is arrested, new vessels cease to form and finally the poorly differentiated cells composing the vessels fail to be replaced and are absorbed. The troublesome port-wine mark is fully developed at birth, the cells are mature, well differentiated and not very active. It can, perhaps, be likened to telangiectasia. To cause an obliterating endarteritis in telangiectasis, spider naevus and port-wine mark requires an amount of treatment that may seriously injure normal tissue."

This was written in 1921 but the more recent publications regarding the use of radium in this class of new growths are for the most part, equally enthusiastic. Clark found that the vascular types of naevi are much more responsive to radium than the cellular and pigmented lesions. Strawberry marks he treated by plaque applications of 80 to 90 minutes with a filtration of 1 mm. brass and 4 or 5 mm. of rubber, taking care to avoid producing much erythema. "A faint level whitening of the skin" was regarded as a satisfactory final result. He also obtained good results on cavernous angioma by using cross-fire applications. When the lesion was upon the cheek, the applicators were placed both inside and outside the mouth, the dose given to the mucous surface being about one-third less than that upon the outside skin.

Of the port-wine marks he speaks more enthusiastically than most of the other writers I have examined. He found radium to be the best curative agent he had ever tried, but admitted that the "end-results are far less proportionately perfect than in the vascular or cavernous type of lesions." In his experience the technique was easier to use in young subjects, though great care was necessary to avoid severe reaction. "It is regularly necessary to stop short of a complete removal of the discoloration, leaving a faint pinkish color, which, however, is apt to disappear considerably with time." Burns found the flat port-wine stain the most difficult in which to get satisfactory cosmetic results. Small marks he was able to remove with quarter- or half-strength applicators, using nothing more than a 1 mm. thick aluminum screen. Extensive marks he found more satisfactorily handled by the ultra-violet ray. All other vascular naevi, he decided were more amenable to radium than any other agent he had employed. "The deeper angiomas require considerable gamma radiation to bring about their involution, and, for this type radium in tubes, radium emanation or full strength applicators should be employed, filtering out at least fifty per cent of hard beta rays, either by brass or lead

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y., May 11, 1927.

filters or by metallic filters combined with distance filtration."

In a period of five years Robinson of New York City treated 81 cases of cavernous angioma and 17 port-wine marks. In his opinion, "splendid cosmetic results should be obtained in almost every case, providing careful methods of radium application are used. In the port-wine marks a super-erythema dose is desired, using a plaque of radium needles, or an unscreened radium plaque." Such applications were repeated every four to six weeks for about a year. For cavernous angiomata he used surface applications from a 50-millicurium radium tube screened with brass and hard rubber, or 10-millicurium needles without screenage. Very deep angiomata require more radiation and less distance, in order to reach the remote parts.

My own experience has in general, coincided with that of the workers quoted. Three cases have been selected to illustrate my methods and the final results in handling naevi of different types.

*Case I*—Baby M. L. G., six months old. Nothing abnormal in delivery, but after birth it was noted that there was a soft mass, dark red in color and about the size of a five-cent piece, upon the nose close to the right inner canthus. The lesion was raised about an eighth of an inch above the level of the surrounding skin. An infantile eczema was also generalized over the entire body, and it was not until this condition had been treated and considerable improvement in evidence, that it seemed wise to undertake any measures for the removal of the naevus.

On March 20, 1926, the first radium application was made, consisting of one millicurie hour of beta radiation, application lasting one minute and six seconds, together with a twenty-five millicurie hour dose of gamma radiation, applied for twenty minutes. Reaction was in evidence about ten days later, and when this had subsided, the lesion was flat and had disappeared except for slight scarring, and a few minute red points still visible in the healed area. September 10, 1926, an unscreened radium emanation plaque delivering a dosage of three-quarters millicurie hour, was applied for twelve minutes, this treatment producing no reaction other than a slight reddening of the surrounding skin, after which there was complete disappearance of the naevus, with excellent cosmetic result.

*Case II*—Baby I. G., 7 months old. After a normal delivery the angioma was observed as a somewhat spongy red mass, about an inch and a half in diameter, slightly raised from the left cheek. This naevus increased in size steadily until at the age of six months it was perhaps an inch and five-eighths in diameter and stood out prominently upon the skin, so that the child was greatly disfigured.

The first application was made December 14,

1925, and consisted of a radium emanation plaque screened with one millimeter of lead, giving an approximate total dosage of 180 mc. hours, length of time of application, twelve hours, giving 25 millicurie hours gamma radiation per square centimeter. Because of the extent of the lesion the plaque was placed in several different positions—"domino fashion." In the course of a couple of weeks the lesion gradually shrank in size, this gradual shrinkage continuing for the next four months. A second irradiation was given on April 20, 1926, improvement being continuous, and on September 26, 1926, a final application was made, consisting of applications of a total of 100 millicurie hours. The cheek now maintained its natural contour, very little atrophy being in evidence and when the little patient was last seen on March 21 of this year, the cosmetic result was very satisfactory.

*Case III*—Female infant of six months. Everything normal at birth except the appearance of a raised area, dark-red in color, and located in the middle of the forehead. When I first saw her this mark had increased to the size of a ten-cent piece and stood up fully a millimeter above the surrounding skin. The treatment consisted in protection of the adjacent normal tissue by a lead shield, and the application of a plaque capable of delivering a twenty millicurie hour dosage. The first application was given July 25, 1925, the plaque remaining in position for 7 hours and 20 minutes. A mild erythema ensued, after which nothing was visible except a few dark red areas in the centre of the original lesion. On December 6, 1925, a second exposure to one millicurie hour of unscreened radium emanation by means of a plaque was made, the actual time of exposure being two minutes and 42 seconds. The final result was a hardly visible whitened scar, and when seen recently the child's appearance was quite normal, as there was no depression and the scar could only just be perceived.

*Case IV*—Baby P. P., three months old was disfigured by a port-wine mark involving the dorsal surface of the fingers of the left hand, with a patch upon the wrist about as large as a quarter, and an area on the back of the hand perhaps one and a half by one and a quarter inches. The skin was a dark bluish red, but could be blanched by applying pressure.

An unscreened radium plaque delivering a dosage of one and one quarter millicurie hours beta radiation was applied for fifty seconds on November 28, 1925. The only reaction was a slight reddening perhaps ten days after, and the mark soon began to become paler and less noticeable. On February 20, 1926, a radium emanation plaque was again applied, the dosage delivered being 50 millicurie-hours gamma radiation per square centimeter. Again a slight reddening was all the reaction which occurred, and the lesion became still more indistinct, being now a light pink color. The

third application was made eight months later, on October 19, 1926, using an unscreened emanation plaque delivering 1.25 mc hours beta radiation per square centimeter for 14 minutes, 45 seconds. This baby has been examined several times since the last treatment, our most recent interview being on April 5 last, at which time there was only slight discoloration upon the hand, the skin seems quite normal in texture without cicatricial tissue, and is perfectly pliable.

Another disfiguring condition which the dermatologist is often called upon to eliminate, is keloid, and here too, radium has proved of signal service. Recent literature has recorded several really remarkable instances where these lesions have yielded to irradiation treatment, when everything else had proved entirely ineffectual. Robinson treated a girl of twenty-two whose eyelids had been completely destroyed by an acid explosion and her face covered with irregular indurated scars. The combined effects of radium and X-ray dissolved these keloids, the eyelids were repaired by a skillful plastic surgeon, and the girl was married three years after the accident occurred. Clark does not think so highly of radium, especially for old fibrous keloids, for though "a soft pliable scar results it does not seem to be the ideal method." However, "the rather severe pain which sometimes accompanies such keloidal formations, is regularly relieved by the first application." Taussig says that though the radium results with keloids are usually good "the exceptions are those of long standing which have become quite thick and hard," and in general, he is inclined to consider radiotherapy before and after surgery to be the best all-round way of handling these cases. Foerster thinks radium especially adapted to the localized hypertrophies found in scar tissue, keloidal bands, and lesions in special locations where cross-firing may be readily practiced. "The aim of treatment is to produce gradual absorption of the growth with the least injury to the overlying epithelium," and for this the chief requisite is the elimination of all soft beta rays. Many workers do not hesitate to employ unscreened radiation, but in his opinion, greater satisfaction can be obtained when gamma radiation alone is secured by using a 0.5 mm to 1 mm thick silver screen, or one of 1 mm of brass, which will produce only a mild erythema. Aluminum and rubber should be used to cut off the secondary rays given off by the primary filtration. Old fibro-sclerotic keloids will sometimes yield to the unfiltered radiation in purposely destructive dosage, but such technique should never be generally recommended.

In my work with keloids, I have placed the greatest consideration on the size and duration of the lesions. It is of paramount importance to irradiate the base, no matter how thick and indurated the particular lesion may be. I do not consider any keloid adequately treated if any thickening at all can still be palpated. For small

areas I use a one-quarter to one-half strength application, screening it only with one-tenth mm of lead, or perhaps four-tenths millimeter of aluminum. This is applied directly to the skin, the exposure lasting from two to four hours. In children this dosage is reduced one-half. The results have been highly satisfactory.

Concerning the use of radium in lupus erythematosus there is still a marked difference of opinion among most experienced dermatologists. Taussig says that in thick, discoid types of this disease radium plaques may be of considerable value, but if the radium therapy does not act favorably at once it should be promptly discontinued. My own observations have led me to believe that in the discoid type we can only hope for atrophy as a result of radium application, and in order to get this, and be assured of eventual healing, we practically always have to repeat the applications. It is wise to place the radium applicators so that they extend well over the normal skin which surrounds the affected areas. In the treatment of the disseminated type of lupus erythematosus I have never used radium as a routine, still relying chiefly upon carbon dioxide snow. I did, however, treat one case of the fixed type, and had the satisfaction of seeing the lesion disappear. My complacency was, unfortunately, of brief duration, for very shortly there was a recurrence at the edge of the scar, and this soon spread so as to re-involve the treated area.

Of pre-cancerous lesions, leukoplakia and senile keratosis are perhaps, the most important. Leukoplakia buccalis which appears as whitish raised patches upon the mucous membrane of the mouth is a frequent forerunner of that most intractable and fatal form of epithelioma, cancer of the tongue, lip or cheek. Syphilis was formerly supposed to be the chief causal factor in producing this condition, but it is the opinion of Schamberg and other dermatologists who have given especial attention to this condition, that trauma, such as that from excessive use of tobacco or ragged edges upon teeth or artificial dentures, is probably of more importance. Whether radium or any other curative agent is employed, the removal of all causes of irritation and the institution of proper mouth hygiene must precede any attempts to eliminate the leukoplakia. These points find typical illustration in the following case.

*Case V*—M. C., an automobile mechanic, aged 49 years. Ten years ago he had been infected with syphilis, for which he had received tardy and inadequate treatment. The Wassermann reaction, however, had been persistently negative for a long time before he came under my observation because of the buccal condition. He was an excessive smoker and in his lower jaw were six decayed teeth with jagged cutting edges. For two years previously he had noticed in his mouth a grayish-white appearance of the mucous membrane, particularly on the tongue and at the oral

commissures Hygiene of the mouth had been instituted, the teeth removed and smoking prohibited, but vigorous anti-syphilitic measures in addition to these precautions had no effect upon the leukoplakia, which seemed rather aggravated than otherwise

Radium treatment was undertaken on April 16, 1926, using an unscreened plaque and delivering a dosage of three millicurie hours per square centimeter, which was disposed domino fashion for a period of fourteen minutes and forty seconds. A severe reaction occurred about ten days thereafter, but on the subsidence of the inflammation the leukoplakia was no longer in evidence. Healing was complete and on the several occasions, when the patient had since been examined, no sign of recurrence has been detected, the buccal mucous membrane appearing normal throughout.

Elderly individuals often present such degenerative processes of the skin as cracks, fissures or warty excrescences on the lips, or patches of seborrhea or keratosis upon other skin surfaces. These are very intractable and resist healing by most ordinary agencies which are effective in younger subjects. No time should be wasted in giving attention to such lesions, for malignancy always lies in wait, and prompt attention to these relatively insignificant manifestations may avert a tragedy later on. These lesions almost always appear on the face or hands, and that exposure to the weather plays an important part in their causation is indicated by the fact that most of the patients are people who spend much of their time out of doors. In some cases I have found that Resorcin and sulphur ointment will completely irradiate these growths, but the majority need more radical treatment, and for this radium serves most satisfactorily, and gives excellent cosmetic results.

*Case VI*—W J, a farmer of sixty-four years. Two years ago he had pneumonia but his history was otherwise unimportant, except that for the past seven or eight years he had noted that there were three dry, scaly spots upon his face, one on the bridge of his nose, a second near the outer canthus of the right eye, and a third upon the right cheek. They had never caused him the slightest inconvenience.

The superficial scales were removed and on July 16, 1925, a radium emanation plaque was applied to the denuded spots, the dosage was one and one-half millicurie hours and the time of application four minutes and twenty seconds. The effect was complete disappearance of the lesions and a good cosmetic result. There has been no evidence of recurrence, and the danger of malignancy is apparently eliminated.

The treatment of frankly malignant skin lesions by means of radium has been much more fully discussed in literature than has that of benign growths, or those which are generally regarded as pre-cancerous. Some of the most spectacular results ever obtained have been on these growths,

and the majority of the earlier articles on the use of radium in therapeutics have been embellished with pictures showing these disfiguring face lesions before and after radium had been applied. There has been but little question as to the value of this element in treatment, and the basal-celled type of growth in particular, has yielded readily when taken in time. The following case is typically illustrative of my rather limited experience in this field.

*Case VII*—C H R, the president of an electric company, 69 years of age, presented a lesion of the cheek about the size of a quarter at the time I first examined him. The growth had been present for two years and had been steadily growing larger. The diagnosis was basal-cell epithelioma.

After removing the superficial crust and necrotic material, application was made of 137 millicurie plaque. The surrounding healthy skin was protected by heavy lead foil and the plaque screened with a millimeter's thickness of lead so as to give only gamma radiation. The applicator was kept in place fifteen and a half hours, thus giving a total dosage of 200 mc hours. In about one month's time thereafter the lesion had healed, leaving practically no scar. The patient died of angina pectoris six months later, but up to the time of death there was not the slightest sign of recurrence.

In all the cases reported I have followed the general technical principles laid down by Dr Joseph Muir of New York, to whom my thanks are due for supplementing my dermatological knowledge with the results of his extensive experience as a radium therapist.

For dermatological work he has designed a plaque, equipped with bare tubes distributed so as to deliver radiation of a uniform intensity over one square centimeter of skin surface. The degree of erythema produced by this plaque can be determined by the length of time the plaque is left in position upon the skin. As the radium containers are unscreened nearly all the beta radiation is delivered, so that, taking 100 per cent delivery as the standard, 3 millicurie hours over normal skin will produce a first degree erythema, and complete destruction of the superficial layer of the skin will be accomplished by 7 millicurie hours. Where no caustic action is desired—as in the flattened type of angioma—2 inch at the outset is sufficient, increasing the dosage by a half millicurie hour in succeeding treatments at intervals of six weeks or two months. When we have to deal with lesions of the basal cell type, such as rodent ulcers, a lethal dose is essential, as deeper structures must be reached.

In the construction of the plaque, a box one centimeter square is equipped with glass capillary tubes containing radium emanation, which are evenly distributed over the bottom. The top is left open, and this open side applied directly to the skin when beta radiation is needed. If gamma

radiation alone is desired, the side against which the radium emanation containers are arranged is equipped with a screen consisting of  $\frac{1}{2}$  mm thickness of lead or silver, supplemented by secondary filtration of aluminum foil and ametal rubber. In the treatment of deep-seated lesions the position of the plaque is reversed, the side containing the filtered radiation being placed against the skin. In applying the beta plaque to large areas care must be taken to avoid cross-firing, and when the "domino-fashion" of application is employed, a space of 2 mm must intervene between each area of skin upon which the plaque is placed.

Dosage is calculated as follows. A beta ray plaque containing 30 mc of radium emanation to

deliver dosage of 3 mc hours  $\frac{3 \text{ mc}}{30 \text{ mc}} = \frac{1}{10}$  hr

or 6 min. Therefore, the time of application of the plaque should be six minutes. The same 30 mc plaque filtered to deliver a dose of 50 mch

$\frac{30 \text{ mc}}{50 \text{ mch}} = 1.66$  hours, or one hour and forty min.

utes application time

In children and infants, one half the adult dosage should be employed

The successful radium treatment of skin diseases requires a combination of experience in this particular branch of medical practice with the clinical use of radium therapy in a wide variety of pathologic conditions. When the dermatologist can command this specialized knowledge either by long personal experience, or by working in conjunction with some one else who has had it, his results are likely to be more immediately satisfactory, and permanently effectual, than under any other conditions.

### THIRD GENERATION SYPHILIS\*

By LEONARD W. JONES, M.D., ROCHESTER, N. Y.

IN the twentieth chapter of Exodus and the fifth verse lies the Biblical authority for the possibility of syphilis appearing in the third generation. "For I the Lord thy God am a jealous God and visit the sins of the fathers upon the children unto the third and fourth generation."

Now whether the reader agrees with Pusey and many others that syphilis did not occur in Biblical times, that it was brought to Europe by Columbus' sailors from America and whether he also holds with many clinicians a grave doubt as to the possibility of third generation syphilis, the fact remains that there is a widespread belief among laymen founded, no doubt, on the words from the second commandment that syphilis can occur in the third and fourth generations and this belief is not confined to laymen alone.

The article on syphilis in the Encyclopedia Britannica supposedly written by Sir Clifford Albutt has this to say on the subject:

"Syphilis may show up in the third generation but on account of the possibility of intermediary infection, it is difficult of proof."

Then in the "Principles and Practice of

Medicine," Osler and McCrae, Edition of 1922 there is this "Is syphilis transmitted to the third generation? The discovery of the treponema answers this question. The disease can be carried through as many generations as are able to reproduce. This makes a thorough study of the family for several generations an important aid in the diagnosis of congenital syphilis."

Franklin Plumley, Chief of the Venereal Clinic of the Rochester General Hospital and the writer believe that we have discovered a family in which there is fairly reasonable proof that the sins of the fathers have descended to the third generation and we present the case-histories of that family for consideration.

The first generation is the grandmother. She consulted me in 1922 with an iritis. She is of foreign birth, is an active old lady, apart from her eye condition is reasonably healthy and yet had a four plus Wassermann.

This grandmother was brought to the office by her young married daughter, age 24. With them was a two-year-old boy. This daughter was a very pretty girl and she and her young son, while not examined for syphilis at the time, showed no external evidences of disease. The

\* Read before the Staff Conference, February 27, 1927, Rochester General Hospital.

boy was a fine healthy specimen, but had had blotches on his face and feet when a baby

A year later this daughter, in her seventh month of pregnancy, brought in this now three-year-old boy with a well advanced case of interstitial keratitis. I accepted the interstitial keratitis as a proof of syphilis in the child and did not take a Wassermann on him but a Wassermann of the father was negative and of the mother four plus

During the period of her pregnancy she had twenty intravenous salvarsans at the hands of her family physician who also treated the boy with mercurial inunctions under the armpit every second night. At the end of her pregnancy she gave birth to a son who has so far shown none of the stigmata of syphilis although he too has a four plus Wassermann

On September 9, 1926, the older boy was brought back to the writer with a swelling over the left side of nose and the tear sac of the left eye. The history was that he had fallen off a porch four weeks ago striking his face. He did not complain of pain but the nose began to swell

An examination of the nose showed marked ulceration of the mucus membrane of the left lower turbinate and he was sent to the Rochester General Hospital for a culture to be made for possible Vincent's. This was negative

The following day the writer removed a small piece of dead bone loose in the nose and presumably from the lower turbinate. He was too unruly a patient to make an exact exami-

nation. At my suggestion his family doctor turned him over to the Venereal Clinic for intensive anti-syphilitic treatment which he is now receiving

In the *Lancet* for January 20, 1923, there appeared the case of a young woman age 23, who came to a London Hospital with interstitial keratitis. C. F. T. East, who reports the case, suspects the girl's grandfather as the guilty party, he having been a soldier on foreign service, dying of senile decay at the age of seventy-one

To quote from East "In the 17th century, Van Helmont thought that syphilis might be transmitted to the third generation, Sanchez expressed the same idea in the 18th century. On the continent lately the idea has found much support. Barthelemy was in favor of it being possible. Fournier has urged strongly that the transmission of syphilis undoubtedly does occur and has collected a number of cases. In Germany, Schultz has supported the view. Sir Johnathan Hutchinson, however, did not agree with this and G. F. Still considers the question undecided"

If there is any weak point in the case we have submitted, it would appear to be a re-infection in the person of the married daughter. Dr. Plumley and the writer have questioned her very closely on certain intimate features of her sexual life and are thoroughly satisfied that her syphilis was transmitted and not acquired

## MEDICAL TESTIMONIALS

The leading article of the Legal Department of this Journal is on the subject, "The Endorsement of Commercial Products by Physicians"

It seems incredible that over eleven thousand physicians who received samples of cigarettes should certify to their non-irritating qualities in testimonials like those of quack medicines. No one would have believed that to be possible unless the manufacturer had sworn that he received

11,105 signed testimonials of doctors in praise of cigarettes

When almost one-tenth of the practising physicians of the United States give testimonials for the price of a small carton of cigarettes, it is high time that the profession gave heed to the suggestion of our legal counsel to embody a condemnation of such practice in the Principles of Professional Conduct.

boy was a fine healthy specimen, but had had blotches on his face and feet when a baby

A year later this daughter, in her seventh month of pregnancy, brought in this now three-year-old boy with a well advanced case of interstitial keratitis. I accepted the interstitial keratitis as a proof of syphilis in the child and did not take a Wassermann on him but a Wassermann of the father was negative and of the mother four plus

During the period of her pregnancy she had twenty intravenous salvarsans at the hands of her family physician who also treated the boy with mercurial inunctions under the armpit every second night. At the end of her pregnancy she gave birth to a son who has so far shown none of the stigmata of syphilis although he too has a four plus Wassermann

On September 9, 1926, the older boy was brought back to the writer with a swelling over the left side of nose and the tear sac of the left eye. The history was that he had fallen off a porch four weeks ago striking his face. He did not complain of pain but the nose began to swell

An examination of the nose showed marked ulceration of the mucus membrane of the left lower turbinate and he was sent to the Rochester General Hospital for a culture to be made for possible Vincent's. This was negative

The following day the writer removed a small piece of dead bone loose in the nose and presumably from the lower turbinate. He was too unruly a patient to make an exact exami-

nation. At my suggestion his family doctor turned him over to the Venereal Clinic for intensive anti-syphilitic treatment which he is now receiving

In the *Lancet* for January 20, 1923, there appeared the case of a young woman age 23, who came to a London Hospital with interstitial keratitis. If there is any weak point in the case we have submitted, it would appear to be a reinfection in the person of the married daughter. Dr Plumley and the writer have questioned her very closely on certain intimate features of her sexual life and are thoroughly satisfied that her syphilis was transmitted and not acquired

## THE INDIVIDUALISTIC DOCTOR

Medical thought, like that along any other line, often goes in cycles. A generation ago the doctor was intensely individualistic, and conducted his practice with little regard for his fellows. Then the specialists sprung up and the family doctor learned to send them his difficult cases.

Next came the medical laboratory with its refinements of histology, chemistry and bacteriology, and the family doctor yielded more of his independence and often relied on the technician for a diagnosis.

Departments of health developed a diagnostic service and compelled the unwilling physician to make an exact diagnosis in con-

tagious cases, and practically forced him to apply the proper remedies which were supplied by the State.

Doctors finally began to wonder where all this yielding of their personal independence would lead, but the predicted calamities failed to materialize. Physicians are more than ever prone to refer their cases to specialists, to patronize the laboratories, and to cooperate with health departments. But now, instead of being dominated by those agencies, they use them as helpers. The doctors are returning to an individualism based on scientific knowledge and impelled by a sense of civic duty toward their medical brethren and the public.

## LOOKING BACKWARD

### This Journal Twenty Years Ago

*Christian Science*—Twenty years ago Christian Science healing was discussed to a much greater extent than at present, and "Healers" were making extravagant claims for their system. This JOURNAL for November, 1907, says:

"Judge Gray, of Indiana, was attacked by the Eddyites in communications to the public press because he rendered a decision unfavorable to that particular cult. When asked for his opinion off the bench, this is what he said:

"The argument that people get well under their ministrations, and that many people believe in the doctrine proves nothing. Thousands of people got well without medicine or prayer or faith hundreds of years before Mrs. Eddy was born. Every educated physician knows that the inherent recuperative forces of the human organism tend to restore the afflicted. The doctor seeks to aid by furnishing favorable conditions. Nature heals a cut. It is only the simpleton who would sing or pray when the gaping wound ought to be sewed up. A broken leg will get well after a fashion, without treatment of any kind, but much sooner and better under intelligent coaptation. Prayer won't set a broken leg and it is humbug to talk about it. Prayer will not destroy the germs that cause consumption, malaria, typhoid, diphtheria or even the itch. The human organism cures, medicine assists. That some good people believe in Christian Science

proves no more in its favor than the same fact proves the infallibility of Mormonism or Mohammedanism. Some people will believe anything, especially if afflicted in body and mind. Sometimes the more ridiculous the proposition the more intense the faith. And then, again, Christian Scientists claim that it is God that does the curing, and that they are the only fellows that can get Him at it. What do you think of that? Now, if God is going to give assistance in curing the sick, why should He not aid the Christian physician who probably knows more about science than a carload of so-called healers? Christian Scientists claim to be the only fellows that are obeying the "dual commandment" to preach the gospel and to heal the sick. Better turn and re-read that commandment again. Here it is: "Go ye to the lost sheep of the house of Israel, and as you go, preach, saying, the kingdom is at hand. Heal the sick, cleanse the lepers, raise the dead, cast out devils." This is the golden text of Christian Scientists. They scold the people because they only preach, while they do the whole thing. But they don't. They violate the commandment constantly. First, they are commanded to go to the lost sheep of the House of Israel. They don't do it at all. They never treat a Jew. Not much. The Jews are too smart to be caught that way. They work on the Gentiles exclusively."

## DOCTOR WILLIAM GILMAN THOMPSON

William Gilman Thompson, who died on October 27th, in his seventy-first year, was one of the best known and most respected physicians and medical teachers of New York City. He inherited a strong sense of social and community help from his father, who was a pastor. He was friendly and honest, and intensely active in everything that he undertook. He filled the chair of professor of medicine in both the Bellevue and the Cornell Medical Schools, and was prominent on the public health committee of the

New York Academy of Medicine for seventeen years. His most recent activity was in the management of the Reconstruction Hospital, where wounded soldiers and those injured in industrial accidents were restored to health and, if necessary, were taught new means of livelihood.

Hundreds of doctors throughout New York State will recall with satisfaction the hours during which they sat under the instruction of Doctor Thompson and caught his enthusiasm and high ideals.

## MEDICAL NEWS

There has been a gratifying response to the appeal for medical news expressed at the conference of county secretaries on September 15, and published in the October first issue of this JOURNAL. The response would not have been forthcoming if the officers and members of the county societies were not already taking a deeper interest in organized medicine and in public health activities. The increased interest became evident in 1924 when it was already sufficiently developed to justify the officers of the State Society in employing a full-time executive editor and an executive officer to do field work. Then in 1925 came the increase in dues to ten dollars per member, which enabled the State Society to broaden its activities and to come into closer contact with the county societies and their members throughout the State. The field of organized medicine has now become so broad that a considerable part of the time of the President is occupied in field work and in conferences with the leaders of allied organizations that are doing public health work. New fields of activity have been opened up, particularly that of graduate education. Courses of instruction have been taken to the members of county societies, and physicians in rural districts have been inspired to undertake new lines of practice, such as immunizing children against diphtheria. While the foundations for these newer

activities were laid by the officers before 1924, their evolution has come during the last four years and their further development will fall on the willing shoulders of the officers who will serve in the future.

The development of the newer activities of organized medicine are recorded in the pages of this JOURNAL to an extent that is surprising to those who will take the trouble to peruse its pages during the last four years. But these records will continually increase as the local societies broaden their scope of work to a degree that is commensurate with that of the State Society.

The standards for the acceptance of medical news was stated by the Publication Committee in an editorial on page 1199 of the November first issue of this JOURNAL. In addition to an increased number of records of society activities which are inspiring models for other groups to follow, there have come a large number of items that have only a local or ephemeral value, however great their immediate interest may be to those members who are already somewhat acquainted with the localities in which the news has developed. This material could be recorded in local periodicals similar to those published by several of the county societies, such as Queens, Bronx and Erie.

## WHAT PART OF THIS JOURNAL DO YOU READ?

Some doctors who take a number of medical journals say that they glance through the indices and mark the articles that interest them. The surgeon marks the articles on surgery and skips those on the eyes and pneumonia. The specialist is interested in the news regarding the societies of his corner of practice.

Everybody should be interested in news regarding the general societies to which the great majority of physicians belong,—the State, the District Branches and the Counties. Every

issue of the JOURNAL contains items which record the progress of the societies in making it possible for doctors to discharge their civic duties. The files of this JOURNAL during the past four years contain what is probably the most complete record of the evolution of modern activities of medical societies. This record will arouse the interest of any physician who follows it month by month.

Get the habit of reading the News Notes of your State JOURNAL.

ceived an immunizing injection of tetanus serum which would definitely have rescued him. A compromise was effected in which damages were assessed jointly on the physician and the insurance company. The author goes exhaustively into the duty of physicians and hospitals to use immunizing injections in order to escape the charge of neglect. Certainly every wound in which earth or street dust has penetrated should be treated thus and no exception is to be made in wounds which have promptly been disinfected or even have been excised outright. Asepsis, including excision when practicable, should also be carried out in full. Every physician, the author says, should keep on hand two vials of antitoxin of 20 units each. In Germany, after a death from tetanus, the government prosecutor takes the initiative to fix responsibility. The size and character of the wound cut no figure and any trivial wound wherein dirt may have entered is suspicious—dog bites even when trivial, contusions as in door jams, splinter wounds, etc. Although the vast number of such injuries will have no bad sequelæ the medical man can take no chances, for death by tetanus shows that there was something omitted from the treatment. The personal belief of the medical man may be disregarded and even if he is sceptical as to the presence of tetanus bacilli in a wound and has doubts as to the prophylactic efficacy of the antitoxin he cannot afford to take any chances—*Munchener medizinische Wochenschrift*, August 12, 1927.

**Final Results of Gastric Resections for Cancer**—Mauritz Persson presents a study of 1,150 cases of gastric cancer, excluding cancer of the cardia, operated upon at the Seraphimer Hospital of Stockholm during the period 1887-1926. Of the 1,150 cases, 361 were resections, with an operative mortality of 28 per cent, 450 were gastroenterostomies, with an operative mortality of 23.1 per cent, and 339 were exploratory operations, with a mortality of 17.1 per cent. Resection was performed on 210 men and 151 women, with an operative mortality of 32.9 per cent and 21.2 per cent, respectively. During the last 25 years the mortality has shown an evident increase from 20 per cent (1902-1906) to 38 per cent (1922-1926). The causes of this increase are the extended indications for resection and a great displacement of material from the feminine to the masculine majority. The number of technically easy cases has been decreasing. Of 200 surviving patients 161 (80.5 per cent) died within five years—61 in the first year, 61 in the second, and 26 in the third year. All the deaths except two were due to recurrence. In addition 12 patients died of recurrence later than five years after operation (from 5 years

and 4 months to 17 years). In all these cases except one the cancer was localized to the pylorus or its immediate neighborhood. None of these patients was operated upon by the Billroth I method. Of 18 patients still living, 17 are well from 7 to 20 years after operation. All of these patients except one, were operated upon by the Billroth II and Polya methods. Thus from the point of view of durability of results the Billroth II and Polya operations have shown themselves to be absolutely superior to the Billroth I operation, transverse resection, and the Kocher procedure. Scirrhus tumors have shown a greater tendency to relapse than other forms of gastric cancer. None of those surviving the operation for scirrhus tumor has remained relapse-free, while of the other patients, 13.9 per cent have had no recurrence. Improved diagnostic methods together with improved technique have tended to increase the number of those who have survived operation and enjoyed many years of good health. But mankind awaits with impatience a better remedy against cancer than the knife—*Annals of Surgery*, September, 1927, lxxxvi, 3.

**Roentgen Sterilization of Women**—Dr C Holtermann discusses this subject chiefly in connection with extragenital affections. There are two distinct types, the temporary and permanent, which latter may be termed castration. Women toward the menopause may be sterilized when pregnancy is not desirable, but in the case of a young woman some vital indication must be present, such as tuberculosis, heart disease, osteomalacia, etc. The operation is much done for adnexal disease, although women with these lesions are usually sterile to begin with, with the aim of relieving the parts from the strain of menstruation. Women with leucemia, pernicious anemia, and other affections who are apt to bleed profusely at menstruation are sometimes subject to sterilization. Temporary sterilization is largely a theoretical procedure and does not seem to have been done for extragenital affections save in isolated instances. It was once assumed that ordinary sterilization was only temporary. The technique is the same for both procedures save that the dosage differs, the permanent sterilization naturally being the simpler of the two, while for the temporary operation the dose is something over two-thirds that for castration. In the latter we can go well above the book doses without fear of doing injury, but to obtain a temporary effect this is, of course, out of the question for success depends wholly on accurate dosage. Sensibility of the ovarian follicles to the rays depends on the period of ovulation, and the greatest resistance is shown by the resting primordial follicle just as the

# MEDICAL PROGRESS

**The Treatment of Whooping Cough**—At the Montreal General Hospital during the past five years whooping cough has been treated by a variety of methods, the results which are summarized by R R Struthers, Mary Childs, and W R Kennedy (*Canadian Medical Association Journal*, September, 1927, xvii, 9) Among the drugs used was a mixture containing phenazone, tincture of belladonna, and paregoric, with which they had no greater success than anyone else. Bromides were of some value, and when used in sufficiently large doses, distinctly prolonged the interval between spasms at night. Ether injections, in children old enough to cooperate, seemed to have a beneficial effect in securing more sleep. Since it seems that convulsions in whooping cough are a manifestation of tetany, as a prophylactic against this manifestation, cod-liver oil was given as a routine in all cases. Luminal was given with some effect, especially in older children, in allaying the fear of spasms and affording longer intervals of rest. Comparatively large doses are required,  $\frac{1}{2}$  to 1 grain three times a day being frequently needed in children six to eight years old. The use of vaccines was more successful. The vaccine was prepared from known cultures of *B pertussis* secured from patients in the clinic and contained five billion Bordet-Gengou bacilli per cubic centimeter (Commercial vaccines were used occasionally). The children received four or five doses of this vaccine, one every second or third day, the doses being  $\frac{1}{2}$ , 1,  $1\frac{1}{2}$  and 2 c.c. The vaccine produced a comparatively rapid fall in the lymphocytes, which was, however, less marked than the total leucocyte fall. This treatment apparently distinctly shortens the total course of the disease—i.e., both the spasmodic stage and the stage of subsidence. Early treatment, that is before the end of the first week of the cough, is necessary to produce any marked effect in shortening the disease. The total course of the disease in the whole series of cases treated by x-rays was shortened more than in those subjected to any other form of treatment. The technique consisted in giving doses of 200 kilovolts, 25 milliamperes, at 50 cm distance, using 1 mm copper and 1 mm aluminum filters. The time of exposure was from one-third to one minute, according to age. The treatments were localized to areas covering the roots of both lungs, anteriorly and posteriorly at each treatment, repeating weekly. The authors' studies indicate that four weeks is a sufficient length of time for isolation.

**Syphilitic Infection from the Cadaver**—Erich Hoffmann of the University of Bonn, has made an exhaustive collection of alleged cases of this transmission, partly through sending out a questionnaire. The gross total is 38 cases, of which 4 are reported without enough documentation, while some doubt as to genuineness is present in 14 more. This leaves a net of 20 properly authenticated cases, the observers of which were mostly men with superior qualifications for diagnosis. With one exception the primary lesion seems to have been on one of the digits. In 15 cases the cadaver was that of a congenitally syphilitic child, the tissues of which are known to abound in spirochetes, and in addition to necroscopists and other medical men the victims included ordinary dead house attendants and laboratory servants. It seems established that transmission may occur more than 24 hours after death. The great rarity of transmission is shown by the fact that men with extensive experience have never encountered a case, but the element of care to avoid cadaveric infection must not be lost sight of. The course of the infection for whatever reason was somewhat paradoxical, for in some cases it was of late supervention, in others overlooked, and there was more than common severity, for three victims presented malignant syphilis and a fourth early cerebral involvement. This severe course appears strange when it is borne in mind that the virulence of the spirochetes ought to be somewhat weakened by sojourn in the dead body, and absence of early and thorough treatment must be charged up as an unfavorable factor. This weakening of virulence if really present would account for the infrequency of cadaveric infection. The view that malignant syphilis is due to an unusually intense allergic reaction determined by low virulence may find some confirmation here, where no less than 3 cases were recorded.—*Deutsche medizinische Wochenschrift*, September 2, 1927

**Responsibility for Tetanus Death**—In a paper by A Krecke discussing the proper time to inject prophylactic tetanus serum, the following forensic case is cited. Last summer a 15 year old boy in climbing a barbed wire fence pricked his foot. Although the wound was trifling, fatal tetanus soon developed. A damage suit resulted with the idea of fixing the degree of responsibility of the attending physician and the insurance company. A university professor testified that had the case come to his clinic the patient would have re-

investigation, an autogenous vaccine prepared from streptococci isolated should be used in addition to removal of the focus. When no infective focus can be found, one should employ a mixed stock vaccine, containing a typical example of the three main groups of streptococci—salivarius, faecalis, and pyogenes. The object is not to make the patient's blood bactericidal to streptococci, since it is doubtful that this can be done, but rather to keep the so-called antibody content of the blood at such a level that all streptococci or their products can be so altered antigenetically that they no longer produce reactions in the joints. With this view in mind it is obvious that very small doses of vaccine should be used throughout the treatment in order to avoid producing reactions in the joints. One million is large enough for the initial dose. The increase should be gradual—from 25 to 50 per cent of the original dose. The interval between the first few doses should be three or four days, but later should be one week. Frequent reactions will make the patient worse and the treatment will do more harm than good. In order to reach doses that will be adequate the treatment must be extended over three or four months. It is advisable to give a second course of vaccine treatment six months after the completion of the first course.

**Swamp Fever**—Under this term O. Werner of Breslau, describes a malady which first appeared in Silesia in 1926. It attacked principally males from 14 to 25 years of age. The incubation period showed extreme variations but was usually 1 to 2 days, and the onset was sudden and sharp although a marked chill was the exception. The picture was that of any acute febrile infection with nothing characteristic. Severe backache and pains in the calves and feeling of pressure in the eyeballs were mentioned. Objectively there was a flushed face and conjunctivitis. The duration of the fever was at the outside 7 days and the highest temperature, which was usually seen toward the end of the fever, was not over 105°. The pulse was never high and at the period of defervescence bradycardia was common. The blood pressure was low. Complications and sequelae seem to have been absent. Thus far nothing has been learned as to the etiology. Diagnosis should present little trouble for, unlike influenza, the disease appears to spare the respiratory mucous membranes. The most distinctive phenomena are the severe pains and bradycardia with normal leucocyte count and absence of polynucleosis. Other brief febrile affections which might conceivably stimulate it are dengue and the pappataci fever, which are, however, not seen in Silesia. An affection described in 1891 as "mire fever" in Germany,

seems to have been quite dissimilar for there was an exanthem in the latter while delirium was also seen. Under treatment any of the analgesic antipyretics may be used, with morphine if the pains escape relief, and adrenalin if the blood pressure goes below a certain level.—*Deutsche medizinische Wochenschrift*, September, 23, 1927.

**Gynecological Foci in Relation to Various Ocular Infections**—L. Mary Moench, in collaboration with W. L. Benedict at the Mayo Clinic, has been making routine pelvic examinations, with cultures from the cervix, for nearly six years in all types of ocular inflammatory lesions, especially scleritis and episcleritis, in an attempt to correlate these lesions with pelvic inflammation in both incidence and extent. There does not appear to be any parallel between the severity of the ocular symptoms and that of the pelvic infection, but the clearing up of the foci in the cervix has been associated in many cases with striking subsidence of the ocular symptoms. The infection is probably streptococcal rather than gonococcal. Whenever there is a discharge, especially of purulent or seropurulent character, even without other signs of endocervicitis, the cervix is considered a probable source of infection. Local treatment is accordingly instituted and an autogenous streptococcus vaccine is administered. In the majority of cases so treated, when other foci have not been demonstrable, the ocular inflammation has subsided and has remained in abeyance for from one to five years or has entirely disappeared. The inoculations are given, in doses sufficient to produce slight local or focal reaction only, at weekly intervals in series of ten or twelve. It is, of course, important to detect and treat the grosser pelvic infections. If definite laceration or long-standing endocervicitis has resulted in hypertrophy, erosion, or cysts of the cervix, a Sturmdorf operation is indicated. Caution should be exercised in the use of the surgical cautery, since this procedure may result in sealing off of the racemose glands in the deeper cervical tissues and, by interfering with the drainage, throw more inflammatory products into the blood stream, thus tending to aggravate the distant metastatic disease. There is also danger of a violent focal reaction in the eye as a result of absorption of protein from tissue destroyed by the cautery. In recent and mild endocervicitis, however, linear cautery of the walls of the canal may be employed. The treatment should be as conservative as is consistent with the eradication of the focus and the importance of the ocular condition.—*American Journal of the Medical Sciences*, October, 1927, clxiv, 4.

maturing follicle shows the least resistance. This cycle has to be taken into account. Roentgen doses which destroy the maturing follicle may spare the resting primordial follicle and hence are suitable for temporary work.—*Klumsche Wochenschrift*, August 20, 1927

**A Method for the Induction of Respiration in the New-Born**—Writing in the *Lancet*, August 20, 1927, ccxiii, 5425, A. Louise McIlroy emphasizes the fact, recognized only during the past few years, that vigorous and energetic methods of treatment of an infant born in a state of shock and suspended animation are a mistake. As a result of considerable research upon the cause of antenatal and neonatal deaths, she reached the conclusion that the supply of carbon dioxide to the infant would make up for its deficiency in the blood. It is well known that respiration occurs as the result of stimulation of the medulla by the reserve of carbon dioxide in the blood. If this reserve is lost by energetic movements, as in artificial respiration, pulmonary function fails to become established unless a fresh supply is forthcoming. The most suitable treatment for white asphyxia is to wrap the infant in a warm towel or blanket, remove the mucus from the mouth and nose, employing aspiration by catheter, if necessary, and when the cord is cut transfer the infant to a cot well warmed with blankets and hot water bottles. If the heart is only faintly beating, stimulants such as camphor or strychnine may be given hypodermically. The mask of an apparatus which the author describes is applied to the infant's face, and a gas mixture of 95 per cent oxygen and 5 per cent carbon dioxide is given at very low pressure. The mask is applied and withdrawn at the rate of about sixteen times a minute. The cylinder is then changed and pure oxygen is given for several minutes. The administration can be carried out in a cot with a curtain or in a special wood and glass "breathing box." The latter, though not essential, ensures an even temperature (75° F for the new-born). After the infant breathes it is placed in a cot and subsequently is cleaned with olive oil. The apparatus consists of a 15 cubic foot cylinder containing the gases, which communicates with a safety pressure apparatus by which the quantity and pressure of the gases are regulated. The slightest respiratory movement will be recorded on a manometer. Ordinarily the rate of flow is adjusted to 2 liters per minute. This gas mixture is also of value in cases of cardiac and respiratory failure under anesthesia.

**Serum Treatment of Scarlet Fever**—Professor Schottmüller of the Hamburg-Eppendorf Hospital, discusses this subject at length, and

it is of interest to note that as far back as 1895 he had recognized the presence of hemolytic streptococci in pure culture in the tonsils and certain other organs of scarlet fever patients. At that time of course, he did not accuse them of causing the disease. The Moser serum which was subsequently prepared from streptococci appeared to have some influence over the disease, and after a long period of latency the Dick toxin and antitoxin came to the front in connection with efforts at immunization and treatment. The author has used the antitoxin extensively in a material of 270 cases seen during the past year. Fifty moderately severe cases were treated with the antitoxin while a control series received no serum. There could be no doubt that the various symptoms attributed to the disease toxin were either improved or abolished outright. In regard to complications there were fewer of these under serum treatment although the ratio was only 2 to 3, and it was evident in advance that many complications cannot be prevented by the serum. Moreover the discrepancy appeared to be chiefly in the number of lymph-node infections which responded to the serum treatment while more severe complications, such as otitis media and polyarthritides, were actually more numerous under serum. Three of the 50 serum patients died, despite the fact that the toxic symptoms had yielded to the antitoxin. The 50 control patients were of a milder type than those of the serum-treated series—in fact the omission of the serum was due to the relative mildness. No deaths resulted in this series which was a justification for withholding the specific treatment. The author has reversed his former position in regard to the specific character of the scarlatina streptococcus for at present the weight of evidence has made it almost certain that it is the specific offender.—*Klumsche Wochenschrift*, September 3, 1927

**Fundamental Principles in the Vaccine Treatment of Chronic Arthritis**—Kenneth Stone, writing in the *Practitioner*, September, 1927, cxix, 3, summarizes the evidence of the infectious nature of rheumatoid arthritis, and suggests that the mechanism by which focal sepsis produces joint disease may be explained by the phenomena of allergy. There is experimental evidence that an animal's joints can be made sensitive to streptococci. The hypothesis seems reasonable that rheumatoid arthritis is a result of a long succession of allergic reactions occurring in joints sensitized to streptococci. The prevention of streptococci from coming into contact with the sensitive joints should relieve symptoms and cause regression of the disease. When the infective focus is still present, and is accessible to bacteriological

investigation, an autogenous vaccine prepared from streptococci isolated should be used in addition to removal of the focus. When no infective focus can be found, one should employ a mixed stock vaccine, containing a typical example of the three main groups of streptococci—salivarius, faecalis, and pyogenes. The object is not to make the patient's blood bactericidal to streptococci, since it is doubtful that this can be done, but rather to keep the so-called antibody content of the blood at such a level that all streptococci or their products can be so altered antigenetically that they no longer produce reactions in the joints. With this view in mind it is obvious that very small doses of vaccine should be used throughout the treatment in order to avoid producing reactions in the joints. One million is large enough for the initial dose. The increase should be gradual—from 25 to 50 per cent of the original dose. The interval between the first few doses should be three or four days, but later should be one week. Frequent reactions will make the patient worse and the treatment will do more harm than good. In order to reach doses that will be adequate the treatment must be extended over three or four months. It is advisable to give a second course of vaccine treatment six months after the completion of the first course.

**Swamp Fever**—Under this term O. Werner of Breslau, describes a malady which first appeared in Silesia in 1926. It attacked principally males from 14 to 25 years of age. The incubation period showed extreme variations but was usually 1 to 2 days, and the onset was sudden and sharp although a marked chill was the exception. In recent and mild endocervicitis, however, linear cautery of the walls of the canal may be employed. The treatment should be as conservative as is consistent with the eradication of the focus and the importance of the ocular condition.—*American Journal of the Medical Sciences*, October, 1927, CLXIV, 4.

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York

## THE ENDORSEMENT OF COMMERCIAL PRODUCTS BY PHYSICIANS

In this present era of advertising and publicity, it has become a widely followed practice for the makers of all kinds of goods to advertise their wares by printing the pictures of well-known men or women together with their endorsements of the product. Thus, we are accustomed to see portrayals of dramatic critics, actors and others smoking some particular brand of cigar or cigarette and certifying that there is nothing like it. The endorsers, we understand, are not infrequently remunerated.

The propriety of this course on the part of those who furnish their endorsements, where such endorsers are members of the laity, is a matter falling within their liberty of choice, and is properly governed by their own sense of the fitness of things. When, however, non-therapeutic agents, such as, for example, cigarettes, are advertised as having the recommendation of the medical profession, the public is thereby led to believe that some real scientific inquiry has been instituted, and that the endorsement is the result of painstaking and accurate inquiry as to the merits of the product.

Despite the frequent attacks upon the medical profession, we believe that the people of this country, take them as a whole, have a regard and wholesome faith in their physicians. All that tends to the building up and strengthening of this faith redounds to the benefit of the medical profession and of its individual members, and that which in any wise tends to shake this faith and confidence works a detriment not only to the profession as a whole, but to each individual practitioner. All that tends to strengthen the faith of the people in the belief that medical opinions are founded upon a sound scientific basis, should be fostered by the profession.

Not long ago the writer's attention was called by various leading practitioners of this city to ascertain advertisements appearing in the lay press which, if the foregoing principles are sound, would not seem to redound to the ultimate benefit of the profession. The advertisements particularly referred to are those widely heralding a certain brand of cigarettes. One advertisement portrayed a young man with a cigarette in his hand standing evidently in a doctor's consultation room, for behind the gray-haired and respectable-looking personage obviously depicted as a physician, there stands a young woman (an exceedingly attractive one) in a nurse's uniform. After display headlines giving the name of the cigarette in question, there ap-

pears this "Then note the *verdict* of 11,105 doctors." The question was asked as to why certain singers, actors and broadcasters had found this particular brand of cigarettes "of no possible injury to their voices," and then the advertisement proceeds "For the answer we turned to medical men and asked them this question 'Do you think from your experience with ——— cigarettes that they are less irritating to sensitive or tender throats than any other cigarettes whatever the reason?' 11,105 doctors answered this question 'Yes.'" There is a footnote to the statement purporting to bear the certification of a firm of certified public accountants "that we have examined 11,105 signed cards confirming the above statements."

We have no knowledge as to whether or not the facts stated in the advertisement are correct, but in the absence of evidence to the contrary, we would be forced to the conclusion that the representations made are accurate, in other words, that the number of physicians certified to, had in fact endorsed this particular brand of cigarettes as "less irritating to sensitive or tender throats than any other cigarettes." We are confident that not a single one of the physicians so certifying had even the faintest idea that such a course might in any wise militate against the best interests of the medical profession.

What probably happened, we presume, is that the company sent to the doctors in question a carton or more of the cigarettes, and then later wrote them asking their opinion of them, to which in all good faith the doctors, no doubt, responded as is represented. We have no knowledge that this was the course pursued, but from our general knowledge as to the way in which advertising campaigns of this kind are conducted, think this is probably a plausible explanation.

By this advertisement, however, the general public is given the impression that there has been a real scientific inquiry as to the therapeutic effect of the cigarettes in question, and that a real scientific investigation has been made, as a result of which the conclusion has been scientifically arrived at that the cigarettes in question were "less irritating to sensitive or tender throats than any other cigarettes." It is highly improbable, to say the least that any such scientific investigation such as doctors make in order to determine the value, let us say, of insulin or other therapeutic agents, had been made. The thinking members of the public must realize this, and those of them inclined towards a dislike or sus-

piction of the profession might unfortunately be led to the conclusion that professional judgment was in some instances tainted with that commercialism which would destroy its scientific value. If this is so, such conclusions would not aid in building up that confidence and respect for medical opinion to which your great profession and its individual members so richly are entitled.

In looking through the principles of professional conduct of the Medical Society of the State of New York, we find no canon which the endorsements referred to would definitely violate. The first section of those principles declares that "Everyone on entering the medical profession and thereby becoming entitled to full professional fellowship, incurs an obligation to advance the science and art of medicine, to guard and uphold its high standard of honor, to conform to the principles of professional conduct and to comport himself as a gentleman." No one for one moment will contend that any physician making a certification, such as is here mentioned, has failed "to comport himself as a gentleman." On the other hand, the question may perhaps be legitimately asked whether such a course tends

"to advance the science and art of medicine and to guard and uphold its high standard of honor."

The suggestions which we have here indicated, we feel might well be a proper subject-matter of discussion among physicians in general in order that definite views upon this subject may be formulated. It is possible that the suggestions here made may not be generally acceptable. If, however, the views herein expressed seem generally satisfactory to the medical profession, to the writer at least it would seem wise if at the next meeting of the House of Delegates an additional article were added to the principles of professional conduct whereby the endorsements by physicians of purely commercial and non-therapeutic agents would be condemned. Such an article would tend to clarify the situation, and would present this question in a definite way to the entire profession. Those, then, who had not considered this matter from the point of view herein indicated, would be furnished in the shape of a definite article, a standard to which all of the profession would promptly and cheerfully conform.

---

### FRACTURE OF RADIUS AND ULNA—PERMANENT NON-UNION

Here it is charged that on April 8th the plaintiff sustained a fracture of both bones of the left forearm, and that the defendant physician was engaged to attend and treat the fracture, that because of the careless and negligent treatment of the defendant, the fractures were not reduced or united, and that the plaintiff has permanently lost the full use of his arm, has been made a cripple and unable to attend to his ordinary business. It is further charged that the defendant had failed to apply the necessary appliances and treatment to keep the broken bones in place or to permit or cause the same to become united, and that because of the defendant's acts, the fractured bones became displaced and did not unite.

This physician had been specializing for a number of years in general and abdominal surgery, and had in the course of his practice attended several thousand fracture cases. The physician was an attending surgeon at one of the hospitals of the city where the plaintiff came under his service for treatment. While the plaintiff was examining a gas engine on April 13th, his sleeve was caught in the fly-wheel, causing a fracture of the radius and ulna. Upon his admission to the hospital on April 15th, an examination disclosed the following: Marked swelling, ecchymosis absent, deformity present, mobility absent, false point of motion present, crepitus marked.

On April 15th, the day of the patient's admission to the hospital, the defendant under a

general anaesthesia of ether performed an operation for the reduction of the fracture. His technic, as shown by the hospital record, was under-extension and counter-extension with manual pressure at point of fracture, at junction of middle and lower thirds of left forearm. The fragments were approximated in good alignment. Provisional side splints were applied, orders being given to place the whole upper extremity in an aeroplane splint with extension bands applied, so as to keep up continuous extension to preserve alignment.

On April 18th, a report of X-ray showed the fracture of the middle third, both bones of the left forearm, position good. On April 20th, the forearm showed poor callus formation, otherwise the patient's general condition was good. An X-ray taken on April 25th showed transverse fracture, middle third, left forearm, radius and ulna, with upward displacement of lower fragment of ulna. On April 30th, the defendant put the patient's arm in a moulded plaster splint. An X-ray taken on May 1st showed a transverse fracture of the middle third of both bones, left forearm with impairment of interosseous space, marked posterior bowing at site of fracture.

On May 2nd, the defendant physician removed the cast, and examined the patient's forearm. Mobility at elbow and wrist were practically nil because of extreme pain. There was a slight amount of tenderness and swelling over the site of fracture. Crepitus was still

elicited There was not much callus formation The patient at this time desired to go home, and was advised to stay at the hospital, but refused to continue, and left the hospital against the advice of the defendant and other physicians

After leaving the hospital, the plaintiff called on the defendant physician at his office, and on May 3rd examination of the arm disclosed that there was no union at the site of fracture, but there was a slight callus formation There was also considerable restriction of movement in the elbow and wrist joints The defendant at this time advised and administered massage of the arm and hand and passive motion of the wrist and elbow Electricity was also applied to the injured parts to improve the nutrition of the whole limb and to induce better conditions at the site of the fracture The splints were replaced after each treatment

Between May 10th and June 14th, the patient visited the defendant at his office six times The findings and treatment of the defendant during this period were that towards the end of May it was considered advisable to remove the moulded plaster splints and use in their place a leather cuff which enveloped the forearm at the site of fracture and above and below for a distance of several inches The patient was advised to move the wrist, elbow and fingers

He was not seen by the defendant from June 14th until July 3rd At his visit in June, the defendant had advised him that a further operation would undoubtedly be necessary, as the defendant's examination disclosed that there was little or no union The patient objected to any further operation On June 3rd, when the patient called on the defendant, he was again advised of the necessity of an open operation, and told to return to the hospital for that purpose Nothing further was heard from the patient until about three months later when the physician again saw the patient at the hospital, and again advised the patient of the necessity of an open operation, to which the plaintiff refused to consent The patient was not again seen by the defendant physician

When last seen by the defendant, the stiffness at the plaintiff's elbow had largely disappeared, there was also marked improvement at the wrist, but not to as great an extent as at

the elbow The movement of the fingers was fairly good

A physical examination of this patient made almost three years after the occurrence of the accident showed that he had an ununited fracture of both bones of the left forearm, that he wears a leather support, that his forearm gives evidences of extensive operation scars which were perfectly healed, but there was no bony union of either bone, and a plate which had been inserted in his arm rattles around, giving no support

About six months after the plaintiff last saw the defendant, he came under the care of another physician who, upon examination, found an ununited fracture of the radius, and advised an open operation, the patient consenting to the same and entering a hospital for that purpose This surgeon performed an open operation, and inserted a Lane plate, after bringing the ends of the fractured bones in apposition After the operation, this surgeon had several X-rays taken, which showed the bones in apposition The patient remained in the hospital for about three months, during which time he had a cast on from his shoulder down to the hand This surgeon was likewise unable to get a bony union at the site of fracture The Lane plate remained in position no infection set in, and all that the second surgeon could see was that the bones would not unite When the second surgeon was convinced that he could not get a union of the fractured bones, he suggested to the plaintiff that the Lane plate be taken out, but the patient refused to undergo another operation for this purpose

After discharge from the second hospital, the plaintiff kept calling on the second surgeon at his office This surgeon then had a brace made for the plaintiff's arm When last seen by the second surgeon, the plaintiff had the use of all of his fingers and hand motion, but there was no strength in the arm, except that which the brace gave him This surgeon does not feel that any form of operation would result in a bony union This surgeon was of the opinion that the artery supplying the radius was injured in the original accident, which thus prevents bone nourishment and is the possible cause of the failure of the bony union

After pending for several years, this action was abandoned by the plaintiff and never brought on trial

# NEWS NOTES

## THE FIRST DISTRICT BRANCH

The Twenty-first Annual Meeting of the First District Branch of the Medical Society of the State of New York, composed of the six counties of New York, Bronx, Richmond, Rockland, Orange, and Westchester, was held on October 20, 1927, in the Concourse Plaza Hotel, 161st Street and Grand Concourse, Borough of the Bronx, under the presidency of Dr Edward R. Cuniffe of the Bronx.

The morning session was devoted to addresses by the officers of the State Society. Dr James E. Sadlier, President, discussed the aims and activities of the Medical Society of the State of New York, dwelling especially on the two phases of the education of the physician, and the discharge of the civic duties in which medicine is concerned. The members of the First District Branch are favorably situated so far as education is concerned. They require little assistance from the State Society, but on the contrary, they can assist the State Society in its program to take the opportunities for education to their brethren in the counties remote from teaching centers.

The practice of civic medicine offers a large field in the First District where great organizations, such as the City Department of Health and Dispensaries, may overshadow the public health efforts of the individual doctor. While a physician, acting alone, can have little influence in the fields of public health, the organizations of physicians can exert a great power in directing public health activities along medical channels.

Dr Thomas P. Farmer, Chairman of the

Committee on Public Health and Medical Education, amplified Dr Sadlier's remarks about medical education and described the courses which are offered to the county societies.

Dr W. Warren Britt, Chairman of the Committee on Medical Economics, described the work of his committee, especially its relation to workmen's compensation.

Luncheon was served at half past one to about one hundred members. Other physicians came to the afternoon meeting, so that the total attendance was about five hundred,—probably the largest at any meeting of the First District Branch.

The afternoon was given over to a scientific session. The first speaker was the Honorable James A. Hamilton, Industrial Commissioner of the New York State Department of Labor, who spoke on the subject "The Workmen's Compensation Law in its Relation to the Physician." This paper was practical, and was well received by the physicians. It is published on page 1238 of the Scientific Department of this JOURNAL.

Dr Russell LaFayette Cecil, of New York City, gave an address on the subject, "Facts in the Etiology of Chronic Arthritis."

"The Indications for Radium Therapy in Intra-Uterine Conditions" were described by Dr William P. Healy of New York.

Dr John DeJ. Pemberton, of the Mayo Clinic, Rochester, Minnesota, described the "Causal Factors in the Surgical Mortality of Exophthalmic Goiter."

## POST-GRADUATE INSTRUCTION

Dr Thomas P. Farmer, Chairman of the Committee on Public Health and Medical Education, announces that the following courses have been recently arranged:

### *Montgomery County Course in Obstetrics Amsterdam Hospital*

October 20th, Prenatal Care, Dr Paige E. Thornhill, Watertown

October 27th, Postpartum Care, Dr Stuart B. Blakely, Binghamton

November 3rd, Pathology of Pregnancy II, Dr James K. Quigley, Rochester

November 10th, Pathology of Pregnancy II, (To be announced)

November 17th, Pathology of Labor I, Dr James Harrar, New York City

December 1st, Pathology of Labor II, Dr Paul T. Harper, Albany

### *Oneida County Courses in Pediatrics*

October 28th, Periodic Health Examinations, Dr L. C. Schroeder, New York City

November 4th, Infant Feeding, Dr Charles Hendee Smith, New York City

November 11th, Malnutrition, Dr Hugh Chaplin, New York City

November 18th, Tuberculosis in Childhood, Dr G. W. Graves, New York City

November 25th, The Importance of the Laboratory in Pediatrics (Nephritis, Pyelitis, etc. Blood and Spinal Fluid Examinations)

December 2nd, Heart Disease in Childhood, Dr John D. Lyttle, New York City

elicited. There was not much callus formation. The patient at this time desired to go home, and was advised to stay at the hospital, but refused to continue, and left the hospital against the advice of the defendant and other physicians.

After leaving the hospital, the plaintiff called on the defendant physician at his office, and on May 3rd examination of the arm disclosed that there was no union at the site of fracture, but there was a slight callus formation. There was also considerable restriction of movement in the elbow and wrist joints. The defendant at this time advised and administered massage of the arm and hand and passive motion of the wrist and elbow. Electricity was also applied to the injured parts to improve the nutrition of the whole limb and to induce better conditions at the site of the fracture. The splints were replaced after each treatment.

Between May 10th and June 14th, the patient visited the defendant at his office six times. The findings and treatment of the defendant during this period were that towards the end of May it was considered advisable to remove the moulded plaster splints and use in their place a leather cuff which enveloped the forearm at the site of fracture and above and below for a distance of several inches. The patient was advised to move the wrist, elbow and fingers.

He was not seen by the defendant from June 14th until July 3rd. At his visit in June, the defendant had advised him that a further operation would undoubtedly be necessary, as the defendant's examination disclosed that there was little or no union. The patient objected to any further operation. On June 3rd, when the patient called on the defendant, he was again advised of the necessity of an open operation, and told to return to the hospital for that purpose. Nothing further was heard from the patient until about three months later when the physician again saw the patient at the hospital, and again advised the patient of the necessity of an open operation, to which the plaintiff refused to consent. The patient was not again seen by the defendant physician.

When last seen by the defendant, the stiffness at the plaintiff's elbow had largely disappeared, there was also marked improvement at the wrist, but not to as great an extent as at

the elbow. The movement of the fingers was fairly good.

A physical examination of this patient made almost three years after the occurrence of the accident showed that he had an ununited fracture of both bones of the left forearm, that he wears a leather support, that his forearm gives evidences of extensive operation scars which were perfectly healed, but there was no bony union of either bone, and a plate which had been inserted in his arm rattles around, giving no support.

About six months after the plaintiff last saw the defendant, he came under the care of another physician who, upon examination, found an ununited fracture of the radius, and advised an open operation, the patient consenting to the same and entering a hospital for that purpose. This surgeon performed an open operation, and inserted a Lane plate, after bringing the ends of the fractured bones in apposition. After the operation, this surgeon had several X-rays taken, which showed the bones in apposition. The patient remained in the hospital for about three months, during which time he had a cast on from his shoulder down to the hand. This surgeon was likewise unable to get a bony union at the site of fracture. The Lane plate remained in position, no infection set in, and all that the second surgeon could see was that the bones would not unite. When the second surgeon was convinced that he could not get a union of the fractured bones, he suggested to the plaintiff that the Lane plate be taken out, but the patient refused to undergo another operation for this purpose.

After discharge from the second hospital, the plaintiff kept calling on the second surgeon at his office. This surgeon then had a brace made for the plaintiff's arm. When last seen by the second surgeon, the plaintiff had the use of all of his fingers and hand motion, but there was no strength in the arm, except that which the brace gave him. This surgeon does not feel that any form of operation would result in a bony union. This surgeon was of the opinion that the artery supplying the radius was injured in the original accident, which thus prevents bone nourishment and is the possible cause of the failure of the bony union.

After pending for several years, this action was abandoned by the plaintiff and never brought on trial.

## COLUMBIA MEDICAL SOCIETY

The annual meeting of the Columbia County Medical Society was held at The Worth, Hudson, N Y, Tuesday, October 4, 1927, President John W Mambert, M D, presiding

Members present Drs Bradley, Collins, Diefendorf, Early, Galster, Garnsey, Mambert, Maxon, Noerling, C G Rossman, Skinner, Shank, Taylor, Tracy, guests Drs O D Chapman, John E Heslen, and Assemblyman Henry James

The following officers for the ensuing year were elected President, Burke Diefendorf, M D, Vice-President, N D Garnsey, M D, Secretary and Treasurer, C R Skinner, M D, Censors Drs Van Hoesen, C G Rossman, Collins, Noerling and Maxon, Delegate to State Society, C L Nichols, M D, Alternate delegate to State Society, H J Noerling, M D Samuel J Post, M D, of Philmont, was elected to membership

The treasurer's report showing a balance of \$100.70 and a membership of 37 was read and accepted as read

The committee appointed to make a survey of needs and requirements of a State Aid County Health Laboratory offered the following report

To the Medical Society of the County of Columbia, the following report is submitted by the undersigned members of the special committee on State Aid Laboratories

1 The committee favors the establishment of a county unit of the State Laboratory

2 After careful canvass, we offer no recommendations for the particular location of this laboratory, feeling that it is a matter to be left to the discretion of the Board of Supervisors

3 From a survey of reports from other counties, where such laboratory units are maintained, the needs of Columbia County can be met within economic limits

4 For information, we state figures that will give approximate costs of a laboratory in counties of this size They vary from \$4,500 to \$8,200, these amounts being equally divided between the state and county It should also be noted that the state individually will give up to \$2,500 for first equipment

5 We recommend that the Society take

steps to present to the Board of Supervisors the need of such a laboratory for the people of the County of Columbia, and give such facts as will show how economically such a unit may be established and maintained

Most respectfully submitted

Henry C Galster,  
Henry J Noerling,  
Frank C Maxon

The report of the committee was accepted

On motion of Dr Galster, the secretary was instructed to petition the Board of Supervisors in the name of the Society in regard to the establishment of a Public Health County Laboratory Unanimously carried

Adjourned for lunch

The meeting was reconvened after lunch with President-elect Dr Burke Diefendorf presiding President Mambert's address on Public Health was well received

The remainder of the program consisted of a comprehensive idea of the Public Health Laboratory by Dr O D Chapman, director of the Bureau of Laboratories of the City of Syracuse, and an instructive address on "Handling the Prostatic Patient" by Dr John E Heslen of Albany

The President-elect appointed the following committees Public Health and Post Graduate Education Dr S V Whitbeck, Chairman, Dr H C Galster, Dr J W Mambert, Dr W D Collins, Dr N D Garnsey, Legislative Dr C G Rossman, Chairman, Drs L Van Hoesen, H J Noerling, F C Maxon, C L Nichols

C R SKINNER, *Secretary*

EDITORIAL NOTE —Accompanying the account of the Medical Society meeting, the secretary sent an excellent newspaper clipping of a column giving a description of the meeting and a summary of those parts of the proceedings that had a special interest to the public Of special interest was the president's address calling attention to local problems in which the medical society should take an interest Another clipping was an editorial comment on the value of the county laboratory These articles are excellent demonstrations of practical health work done by a county society

## ESSEX COUNTY

The annual meeting of the Essex County Medical Society was held at the John Hancock Building, Ticonderoga, N Y, October 4th, 1927, with the President, Dr W T Sherman presiding Members present Drs J P I Cummins, T Cummins, W T Sherman, T I

Dowd, C M Sarlin, M E Sargent, G Knapp and L H Gaus Visitors Dr A Saulter and Dr A M Dickinson, Albany, N Y

The following officers were elected President, J Evans, M D, Vice-President, C M Sarlin, M D, Secretary and Treasurer, L H

## WASHINGTON COUNTY

The annual meeting of the Medical Society of the County of Washington was held at Hudson Falls on October 4, 1927, beginning at 4 30 P M with ten members and seven visitors present

The treasurer reported a balance of \$67 93 available

The report of the comitia minora was given, consisting mainly of preparations for the annual meeting

The following officers were elected for the year 1928 President, Dr S T Fortune, Vice-President, Dr W S Bennett, Secretary, Dr S J Banker, Treasurer, Dr R C Paris, Censors, Drs B C Tillotson, L M White and J E Armstrong, Committee on Legislation, Drs W A Leonard, R E LaGrange and D M Vickers

Dr W A Thomas was elected a member

Dr Rogers for the public health committee

reported that a new nurse had been employed and that her work was going on smoothly

Dr Munson reported that one prenatal clinic had been held with ten patients

The annual dues of the society were raised to two dollars

Dr R C Paris, Jr, D D S, read a paper on the relation of dentistry to general medicine.

The members dined together at the Carleton

In the evening meeting it was voted to approve the recent action of the Cattaraugus County Medical Society in its stand taken to support a modest county Health Department without the aid of the Milbank Fund

Dr William A Krieger gave a paper on sinus disease in children

Dr M Smith gave a paper on the advantages of controllable spinal anesthesia to the general practitioner, illustrated with motion pictures

S J BANKER, M D, *Secretary*

## HERKIMER COUNTY

The following news item is of interest, because it illustrates the manner in which the country districts are being denuded of their doctors

Dr Edgar C Swift, the only practitioner of the town of Warren, Herkimer County, died on September 21, aged 70 years, after a general breakdown. He had practiced medicine in the town of Warren for forty-six years and was

prominently identified with the civic and social activities of his town. The community is now left without a doctor, for the nearest physician is seven miles away. Dr W B Brooks, Secretary of the County Society, writes, "If only some Doctor would go to Warren he would make a nice living and more. The winter practice would be hard, but the summer would be delightful."

## COUNTY OF SULLIVAN

The Medical Society of the County of Sullivan has taken a stand in regard to Public Health work and is represented by a committee consisting of Drs Rayevsky, Van Keuren and Payne in the reorganized Sullivan County Health Association, which is the old Sullivan County Tuberculosis Association (a branch of the State Charities Aid)

The Committee consisting of five members, three from the Medical Society, and two from the Sullivan County Health Association, have

the direction of the public nurse. The nurse has done excellent work in the anti-diphtheria campaign and we are shortly beginning another type of school work

In November we are starting our second series of post-graduate lectures. Last year's lecture course on gastro-enterology was excellent and well attended—also the two lectures on cardiology

LUTHER C PAYNE, *Secretary*

county secretaries in Albany, on September 15th, when he described the activities of the County Society in relation to the location of the Oneida County Society.

The Committee on Obituaries made notice of the deaths of Drs O W Burhyte, M J Vies, and C D Hart.

Drs Frederick L Patry, James G Douglas, El H Adams, H N Wallace and Neil D Wick were elected to membership.

The meeting was then turned over to Professor Betts, who explained the various types of deafness which could be treated in the school, and described the ways of reclaiming these deaf children and educating them to be useful citizens.

Miss Wildt demonstrated with her class the mechanism of speech, giving some of the first steps in developing speech, teaching the movements of sounds, words and sentences.

Miss Struppler demonstrated the vowel sounds as the initial steps in building a vocabulary, showing how the sounds are conveyed to the child and how the child reproduces them.

Miss Vaughan gave a demonstration of acoustics and tactile impressions, showing how the child may receive vibrations through the finger tips and reproduce spoken sentences. She also showed how the piano could be used to impress rhythm work upon the children.

Professor L M Elstead, Principal of the Wright Oral School of New York, gave a talk on the subject of "Hard of Hearing" and demonstrated an electric testing device which is essential before determining what type of teaching is most beneficial to the child.

Professor Joseph Keating gave a brief discourse on the subject of stuttering and stammering, and showed how they could be corrected.

The interpretation of the subject was new to most of the physicians present, a large number of whom readily confessed their inability to advise patients intelligently for such treatment. One of the great values of the instruction was that it showed the physicians where they may go for advice regarding correction of defects of hearing and voice.

WM HALE, JR, M D, *Secretary*

---

## CLINTON COUNTY

Clinton County has joined the ranks of those county medical societies which issue their own bulletins. Bulletin No 1 contains a two page program of the annual meeting of October 18th. It also contains the following announcement of a post graduate course, similar to that which was given in Montgomery County in March, 1926, and reported in the August 15, 1926 issue of this JOURNAL.

"The committee has secured Dr Harris A Houghton of New York City to give a course in Cardio-Nephritis. The course will consist of six sessions, each session being a combined lecture and clinical demonstration. Beginning with the mildest type of case, discovered usually by accident or on routine physical, with slight elevation of blood pressure, and perhaps a trace of albumin in the urine, but no symptoms, the moderately and far advanced types of cases will be considered. As far as possible actual patients will be secured for clinical demonstration of the effects of diet and other treatment and observed from week to week. Both hospitals and the physicians of Plattsburgh will cooperate in securing clinical

material, laboratory work and the keeping of records.

"Glycosuria and diabetes incident to high blood pressure will be taken up and one session will be devoted to the metabolic preparation of cases for operation.

"At the conclusion of each meeting Dr Houghton will briefly discuss any articles on Metabolism that have come out in the last Journal of the A M A and he asks that everyone bring his last Journal with him.

"Dr Houghton comes to us well recommended, having given a similar course last year at Amsterdam, which was well attended and highly appreciated by all.

"The meetings will be held Monday afternoons at 3 30 beginning October 24th, at one of the hospitals in Plattsburgh (due notice being given in each case) and will last about one and one-half hours.

"In order to make proper provision for attendance, etc., all who desire to take advantage of this opportunity are requested to fill in and mail the enclosed card promptly. Separate reminder notices of each session will be sent to all who register."

tific methods by mothers endowed with a smattering of psychology, have often been misfits in a social and family sense. Mothers are sometimes misled by the salacious doctrines of the Austrian school into unwise sex education of their children. 'Sex' should be faced frankly, but only when the child reaches need for knowledge—not before."

Dr Sachs emphasized the custom of relegating the early training of the child to the

busy mother's duty, when the growing child needs the father's point of view and training. In the laboring and middle classes especially, fathers tend to shirk family duties. Child guidance needs the attention of more fathers.

The volume of the applause and the lively discussion groups formed as the audience was leaving, indicated the popular appeal of the program of the evening.

---

## TOMPKINS COUNTY

The October meeting of the Tompkins County Medical Society was held in the Chamber of Commerce parlors, Ithaca, N. Y., Thursday evening, October 20th. The reading of the minutes of the last meeting was dispensed with.

The report of the Comitia Minora was made by reading of the minutes of the August meeting.

President Leo P. Larkin then announced the appointment of the following as composing the Committee on Public Relations: Dr. H. E. Merriam, Chairman, and Drs. L. T. Genung and Minor McDaniels.

The Secretary read a communication from the A. M. A. urging the cooperation of County Medical Societies in the Program of "American Education Week," November 7-13 next. Dr. L. T. Genung, School Physician of the city of Ithaca, stated that so far as he knew, the Board of Education has as yet made no plans for its observance, but, if they did so, he had no doubt they would welcome the cooperation of the County Medical Society.

After some discussion as to how the society could best do this, the following motion was made, seconded and passed: "Resolved, That it is the sense of this meeting that it is desirable for the Tompkins County Medical Society to put on one or more additional public lectures."

President Larkin then introduced the speaker of the evening, J. P. Garen, M.D., of Olean, N. Y., President of the Cattaraugus County Medical Society, who gave an address on the subject of the experience of the medical profession of his county with the Health Demonstration there, as administered during the past five years by the County Board of Health and the State Charities Aid Association, as disbursing agent for the Milbank Fund. These two agencies have disbursed, or had at their disposal during that time, approximately \$550,000. Dr. Garen was emphatic in believing that county health units, if wisely operated, are the best way of caring for public health problems. Cattaraugus county physicians are not opposed to a county health unit as such, but to the details of its operation under the Milbank Demonstration. Dr. Garen felt that the control of county health organizations should be within the county and not in the hands of any outside lay organization. The physicians in each county, he said, were best able to study and know the local situation.

After some discussion, and questions asked and answers given, the society gave Dr. Garen a vote of thanks, and then for a time resolved itself into a social gathering before dispersing.

WILBUR G. FISH, M.D., Secretary

---

## SCHOHARIE COUNTY MEDICAL SOCIETY

The seventieth annual meeting of the Schoharie County Medical Society was held in the Hotel Augustan, Cobleskill, N. Y., on Tuesday, October 18, 1927. The meeting was called to order by the President, Dr. Meleatus Bruce.

The officers for 1928 were elected as follows: President, Meleatus Bruce, Vice-President, C. L. Olendorf, Treasurer, L. R. Becker, Secretary, H. L. Odell, Censor, W. T. Rivenburgh, Delegate to State Society (with power of substitution), J. J. Beard.

Legislative Committee, H. R. Bentley, Chairman, L. R. Becker, C. L. Olendorf and D. W. Beard.

Public Health Committee, H. L. Odell, W. S. Pomeroy and L. Driesbach.

Publicity Committee, J. J. Beard, C. L. Olendorf and H. R. Bentley.

Public Relations Committee, E. S. Simpkins, M. Bruce and H. L. Odell.

Treasurer, L. R. Becker, reported all bills paid and a balance of \$103.36 on hand.

## MEDICAL SOCIETY OF THE COUNTY OF MONROE

At the regular meeting of the Medical Society of the County of Monroe, on October 18, 1927, Dr James E Sadler, President of the Medical Society of the State of New York, gave a comprehensive summary of the various activities of the State Society

Dr J S Lawrence, Executive Officer of the State Society, gave an address on the subject "A County Health Unit" explaining the history of the development of such an idea, its purposes and possibilities. There was considerable discussion of the subject by a number of the members, the general trend being that the Society

should reserve any definite expression of opinion on the matter until it should be demonstrated that such a unit would be an improvement on the present method of doing public health work in this county, and a definite plan or program, in detail, for such a unit should be presented. With this in mind, on motion, it was unanimously carried that the President appoint a committee to investigate and study the question, reporting to the Society at a future meeting.

J P HENRY, M D, *Secretary*

## KINGS COUNTY MEDICAL SOCIETY

The first fall meeting of the Medical Society of the County of Kings was held in the McNaughton Auditorium of the Society's building, on the evening of October eighteenth. After a short executive session reviewing the applications from those seeking membership, the major part of the evening was devoted to a scientific program considering the adolescent individual and crime.

The speakers of the evening, together with the titles of their addresses follow:

"Adolescent Mentality and Crime," by Dr John F W Meagher

"Juvenile Crime and Its Cure," by Hon Charles J Dodd

"The Child and the Man," by Dr Bernard Sachs

Without any collusion or prearrangement, their addresses agreed to remarkable degree in placing the cure for crime in the home.

When President Thurston S Welton rapped with his gavel to open the first of the stated meetings, he faced an audience filling the auditorium and overflowing into the rear aisles. Included in the audience were many women guests who were attracted by the popular appeal of the scientific program.

Dr John F W Meagher, who has had much experience as the official examiner of those indicted for major crime, pointed out four factors in the criminal makeup—defectiveness, psychosis, psychopathic personality and character traits. The three forces combatting crime are conscience, religion (call it "ethical sense" or "social values" if you will), and law. He admired Osborn who has said "the aim of punishment is reformation," and he scored a noted lawyer for stating that any criminal who says he wants to reform is lying.

Honorable Charles J Dodd, District Attorney of Kings County, prefaced his address by expressing his appreciation for the courtesy and professional manner with which members

of the medical profession have conducted themselves as witnesses, and in other roles in Court. He punctuated his address by citing some surprising statistics. The age incidence of offenders convicted of felony in Kings County is 32 per cent under 21, and 18 per cent under 25 years of age. In New York City during 1925, 1,190 children were charged with burglary, and 1,334 with stealing. The cure he suggested is to lessen not only parental neglect, but also parental overindulgence, and try to teach children obedience to law and respect for authority. He deplored the closing of playgrounds after school hours and urged that there be more ball parks and recreation centers.

Dr Bernard Sachs, former President of the American Neurological Association, in his address said, "Do not let the 'bogey of heredity' poison your minds and do not put forth the doctrine of heredity as an excuse for inefficient parental care and improper educational methods."

"Development of character requires early training while the child is still imitative. Then the family and the physician have the best opportunity to persuade the child to abandon bad habits. Children should associate with others after the age of 1½ years to learn tolerance. A good regime is to develop kindness and industry as early as possible. Then combat lying. He suggested that boys and girls should play together up to the ages of ten to twelve, after which the sexes should be segregated, for ours is a 'sex-age,' and sex is ever before the adolescent eyes through the motion pictures, drama, books, dances and prevailing styles of dress. Even child study is 'over-sexed'."

"Freudianism" is in vogue mainly because of its appeal to women who subconsciously enjoy the titillation to their libido when being quizzed by men on so intimate a subject.

"Children who are raised on purely scien-

## DIABETIC FLOUR

Diabetic flour was designed to reproduce a bread that contains little or no starch or sugar. The greatest demand for it comes from those persons who had diabetes, and who had been ordered to live on a diet low in starch and sugar. The modern science of nutrition shows that diabetic flour also has an enlarging field of usefulness in forming balanced diets in rheumatoid conditions, intestinal disorders, and overweight.

To design a balanced diet that is satisfactory to the patient is both a science and an art whose application requires much skill on the part of the doctor or the dietitian. The most difficult element to estimate is the carbohydrate. Protein is readily obtainable in meat and cheese, and fat is available as butter, and the amounts of food rich in both of those elements may be easily increased or diminished to the satisfaction of the patient. But most common foods—the vegetables, the cereals, and the fruits—contain carbohydrates in great excess of that required to form a balanced diet, and if these foods are restricted to supply the proper amount of carbohydrates, the body starves from the lack of the proteins and fats.

All people have their peculiar food habits which are hard to change. Americans like plenty of bread and other cereals, and it is largely from these that the excess of carbohydrates come. If therefore a patient could obtain a bread or cereal that is free from carbohydrates, he could probably eat a satisfactory quantity of fruit and vegetables, and yet not exceed his allowance of starch and sugar.

A bread which patients will continue to use must taste nearly like ordinary bread, or else they will tire of it, and will not eat it. The bread must also be as easy to make as ordinary bread, or else it will often not be made. These conditions are well met by some of the preparations on the market.

Diabetic flours are of two classes according to their bases:

- 1 Casein flour
- 2 Gluten flour

A flour which is actually free from starch and sugar has casein as its basis. About two-thirds of the casein is ordinary insoluble casein, and one-third is sodium caseinate which is soluble and forms a sticky solution like that formed by gluten. The stickiness of the soluble casein may be judged by the fact that it is the basis of the glue which is used in making airplane propellers. The soluble casein gives the quality of maintaining lightness to the flour after the dough has risen. The in-

soluble casein takes the place of the starch in giving tenderness and texture to the bread.

Another ingredient of diabetic flour is hemicellulose which is derived from a tropical nut which consists almost entirely of the pure substance. This is ground to particles about the size of those of the finely ground bran, but since it is pure white, its color in the flour or loaf is not noticeable.

Hemicellulose can not be digested by the human digestive juices, although cattle digest it readily. Its use is to give bulk and texture to the loaf.

Since the flour has casein for its basis, it is rich in minerals. The flours on the market also contain leavening material and are self-raising.

A typical diabetic flour—one that is accepted by the Council of the American Medical Association—has the following composition:

	<i>Per cent</i>
Protein	70.9
Ash	5.3
Fat	0.7
Leavening, fiber, etc	13.0
Moisture	10.9
Starch	None
Sugar	None

A low calory flour suitable for bread and muffins may be made by combining the casein and hemicellulose in varying proportions. A vegetable gum having a composition resembling that of gelatin is also used in order to supply the sticky quality which is lacking when only a small percentage of casein is used.

A bran made starch-free by cooking under high steam pressure, hydrolysis by enzymes, and washing, is also used in making dry breakfast foods resembling the common flaky foods that are on the market. The use of bran, hemicellulose and gum makes it possible to prepare a tasty breakfast dish which has no food value at all.

The second class of diabetic flours is prepared from gluten as a basis, but gluten bakes to a hard flinty crust which can scarcely be eaten. Since gluten is a by-product of the manufacture of starch, it is cheap and theoretically should be adapted to making flour. But practically it is mixed with ordinary flour. A gluten flour is really a high protein flour. The government enforces the requirement that flour must contain 40 per cent of gluten in order to be labelled gluten flour, but it still contains about 25 per cent of starch and sugar.

It was voted that Section 4, Chapter IX, of the By-Laws be amended to read, "Five members shall constitute a quorum" A motion was duly made, seconded and carried that one hundred copies of the amended By-Laws be printed

A recess was taken for luncheon, after which a scientific session was held

Dr George E Bellby, of Albany, N Y, pre-

sented a most excellent and helpful paper on "Goiter"

Dr Arthur Sautter, of Albany, N Y, read a paper on "Skin Diseases"

The excellence and timeliness of the papers, their full discussion and the clinic made this meeting a very profitable one to all present

H L ODELL, M D, *Secretary*

## BRONX COUNTY MEDICAL SOCIETY

A regular meeting of the Bronx County Medical Society, held at Concourse Plaza, on October 19, 1927, was called to order at 9 P M, with the President, Dr Friedman, in the Chair

The following physicians were elected to membership

Nicholas Michelson  
Anthony Misco  
Meyer S Rednick

Dr Boas, for the Committee on Public Health and Medical Education, reported on the results of the Periodic Health Leaflet Campaign and urged the members to obtain the blank examination sheets from the Bronx Committee of the New York Tuberculosis and Health Association, 400 East Fordham Road

Dr Lukin, for the Committee on Medical Economics, reported regarding the problem of Open Hospitals

Dr Weitzner, Chairman of the Social Committee, reported on the activities of the Committee for the past year and also on the proposed coming affair

The Secretary, Dr Landsman, presented the report of the Nominating Committee

The President presented Dr Edward R Cunniffe, President of the First District Branch Dr Cunniffe outlined the program of the Annual Meeting of the First District Branch, which is to be held on October 20th Inasmuch as it is the first time that the Bronx County Medical Society has been hosts to the First District Branch, he urged the members to attend the meeting as well as the luncheon that will take place between the morning and afternoon sessions

The program of the evening then proceeded as follows

1 Address by James E Sadlier, President of the Medical Society of the State of New York

Dr Sadlier expressed his pleasure at the report of the Committee on Public Health and Medical Education and discussed at length the subject of Periodic Health Examinations He then dealt with the appointment of the Public Relations Committee by the State Society In order that that step shall be effective, each county organization should have its Committee on Public Relations cooperating with and leading the various health agencies in the respective counties Dr Sadlier also dealt at length with the subjects of Public Health and the Medical Practice Act

2 Address by Joseph S Lawrence, Executive Officer of the Medical Society of the State of New York

He discussed the research work of the State Society He stated that the new General Bronx Hospital should not be alone for the care of the patient but should be for the general advancement of medical practice in the community He then dealt at length on the subjects of the enforcement of the Medical Practice Act, the medical aspects of the Workmen's Compensation Law, and public health activities

3 Paper Involvement of the Nervous System in Diseases of the Blood, Joshua H Leiner

4 Pathological Slides, Arthur Weil

The paper was discussed by Drs S Philip Goodhart, Moses Keschner, Israel S Wechsler and Dr Ginsburg

I J LANDSMAN, M D, *Secretary*

## RATING A PHYSICIAN

How nice it would be if every physician were rated publicly as to his ability! Some people seem to think it can be done, and at any rate they act upon that supposition. Every successful physician maintains his prestige because of the spontaneous recommendations of those whom he has treated. If a doctor is successful in one case, the natural conclusion of his patients is that he is likely to be successful in all other cases that he treats.

It is at this point that the element of character enters. The reliable doctor will know his own limitations, and will not assume a knowledge that he does not possess. Whatever his appearance of confidence and assurance may be to the patient, he will quietly seek advice so that every available means of diagnosis and treatment is utilized. A fundamental requirement of a physician is character. Doctors make an accurate estimation of the character of every one of their fellow practitioners, and they rate character above professional ability and knowledge. They expect a doctor to apply every bit of his ability to a case, and to seek professional help when he has exhausted his own resources. It is to the great credit of doctors that they will go freely to the assistance of a brother doctor when he needs help in diagnosing or treating a case.

These thoughts were inspired by a letter in the *New York Times* of September 8, referring to the death of a boy who was treated for plain stomach ache during four days, following his injury with the bullet of a for-

bidden rifle. The correspondent suggests that the mistakes of doctors be published so that "their records" may be considered when selecting a doctor. A bureau should be established somewhat along the lines of the commercial and financial bureaus referred to by business men when they desire to get a line on a firm or an individual. A standard should be set and a doctor rated according to his skill and ability. His financial success may or may not be a worth-while index. Competent physicians would doubtless welcome a "weeding-out plan."

The correspondent confuses reliability of character with professional ability. Sloppiness and carelessness in making physical examinations are elements of character rather than of professional ability.

Doctors deplore sins of professional omission quite as much as those of commission, but they unanimously oppose publicity as a remedy for the sin or a corrective of the sinner. If a doctor is rated for his mistakes, so also must he be for his successes—and his reputation for either may be entirely undeserved.

It cannot be that the *New York Times* believes in the suggestion of its correspondent. This is an example of a letter which affords an editor an opportunity, or excuse, for calling attention to a matter without his assuming the responsibility for originating it. The device of a letter is the mildest possible way of calling attention to a condition which requires a remedy.

---

## EVANGELISM AND MEDICAL PUBLICITY

The *New York Herald Tribune* of September 19, says, concerning church evangelism:

"The high cost of converts has determined a number of influential church leaders identified with the Federal Council of Churches on a change in the time-honored methods of evangelism. Instead of exhorting the crowd they would go direct to the individual, instead of the tactics of the showman and the effort at an emotional stampede they would use quiet personal persuasion, instead of the professional evangelist they would employ the devout layman."

Some of this same movement is taking place among public health workers, for in place of mass influence of health centers and state medicine, and widely advertised demonstrations, there is evolving the plan of individual

effort by physicians and lay workers. This plan is not opposed to organized effort, but on the contrary, it lies at the foundation of the practice of medicine by organizations of both physicians and laymen. If impersonal influences could reach the people, the churches would have found it out long ago. Health centers, state medicine, and even health demonstrations are too impersonal. The work of physicians is personal. A family doctor has the best opportunity in the world to educate his families in health matters, and next to him is the public health nurse whom he recommends and supports.

If the people of the world are to be saved in health, their salvation will come through the personal influence of their family doctors.

# THE DAILY PRESS

## OPIUM PRODUCTION

The amount of opium that is grown annually is ten times that which can be used legitimately, the rest is used for narcotic purposes whose effects are universally conceded to be bad. The government of Persia, one of the great opium-producing countries, is trying to control the production of the poppy, and has decreed a ten per cent reduction annually for three years. However, the government is finding the same difficulties that confronted the United States in freeing the slaves, for the people have come to depend on poppy raising for one of their great means of support. Those who raise poppies in Persia have little concern for the moral degradation of those who smoke the opium five thousand miles away.

The statesmen of the leading nations are giving heed to the protests of the government of the people who are suffering from the use of opium, and the League of Nations is bringing great pressure to bear upon the governments of the poppy-growing countries to restrict its production to legitimate amounts. Persia is responding, but in doing so it is confronted with the probability of subjecting its own people to suffering in an amount greater than that of the people who are the ultimate buyers of the opium. A great economic situation cannot be disrupted without producing wide-spread suffering.

The *New York Times* of September 15, commenting on the attitude of Persia, says editorially

"Persia is not yet equipped with the means of transportation for bulky goods. The problem has been to find substitute crops that can be transported though the building of roads, and the consequent increasing use of motor vehicles will make it less necessary to think of weight and bulk. The commission, under the chairmanship of Frederic A. Delano, who at great personal sacrifice, undertook the survey, recommended, first, the substitution of food crops and silk for opium, second, the adoption of intensive agricultural methods beginning with simple improvements which the farmers could themselves apply, third, the development of home industries (as the spinning of silk in the homes, which would reduce the bulk to be transported), and, fourth, the improvement of transportation. This is a large order for a people who are as a whole poor—'very poor', who have suffered from famines, disease and civil war, who have but scanty rainfall except in the north, and so much depend upon irrigation, who find it difficult to change their ways of doing things, and who are, moreover, generally without the opportunities for education in new methods.

"Persia sets an example of courageous abnegation as she undertakes to change her culture of centuries for the sake of the rest of the world though to her own immediate loss."

## WHY PEOPLE GET HURT

The *New York Times* of September 7 has an editorial on the statistics of accidents affecting human life and health. The greater proportion of crippling accidents occur as the result of industrial pursuits. These are charged against the industry, even when the individual and not the industrial establishment is to blame. The *Times* rightly questions the reliability of accident statistics when it says

"The chief present need of the safety campaign is better facts about the real causes of accidents. Usually many possible causes are involved. Some are human, the victim or his companions did something wrongly. Others are material, some tool or machine or floor board or other object behaved in the wrong way. It is difficult to sort these out. When a workman slips on the floor and falls against a machine that mischance may be ascribed, often with equal justice, to careless walking, to too smooth a walkway, to insufficient lighting, to a machine unduly exposed, or to any one of a dozen other causes. Who shall say which is the one cause that is to appear in the report and thence in the accident statistics?"

"The isolation of cause and effect, which is an essential of the scientific method, is a Procrustean expedient when applied to the real world. Facts must be stretched, others lopped off, until some kind of fit is obtained. It is to be suspected that present-day accident reports, upon which the statistics are necessarily based, do not fit the facts of accident causation as well as they might. Here is an important problem for industrialists, engineers, physicians and psychologists. All of them will be needed before it is solved."

An element that is not always considered is the tendency of those hurt to magnify their injuries in order to collect greater compensation. Ambulance surgeons are well aware of the fact that the victims of accidents wish to have the seriousness of their injuries made as great as possible. A sprain is a break, fear is shock, and loud outcries are the expressions of intense physical pain. Physicians often find that attendance on accident cases is an undesirable burden, both at the time of the injury and later when he is dragged into court an unwilling witness.

tal problems. Indeed, there were not a few who looked upon it as a fad, and spoke of it disparagingly. Dr. Berman, who has popularized the subject of endocrinology, especially in its relation to behavior and its disorders, obviously belongs to the latter group. In fact, he did not hesitate to broadcast his views, and he did so in a most interesting little book, called *The Religion of Behaviorism*. He develops his theme in a rather convincing manner, tracing the genesis of Behaviorism, and proving its utter futility in helping to understand human problems. In so doing he indirectly praises the Gestalt theory, and offers it as a substitute to those individuals who are still engrossed with Behaviorism. It is a rather interesting little book, and goes a long way in proving the contention of those who have long maintained that there are too many people who are unfortunately unprepared either by training or experience, who readily offer advice in mental problems.

I J SANDS

**CITY HEALTH ADMINISTRATION** By CARL E. McCOMBS, M.D. Octavo of 524 pages. New York, The Macmillan Company, 1927. Cloth, \$5.50.

This is a complete volume of public health and welfare administrations as applied to the communities of all sizes. The author divides the volume into three parts: Municipal Health Functions, Organization and Administration of Sickness Prevention Functions, Organization and Administration of Sickness Treatment Functions. He gives the relation of municipal to state functions and the various forms of organization under a mayor and city council form of administration as well as the commission form of city administration and the manager form of city administration. He goes minutely into the various functions to be performed by health departments and public welfare departments in small as well as in large cities and draws from a great amount of personal information as well as literature to illustrate the various forms of administration. Altogether, the book is complete and will be found a valuable reference volume for any person engaged in public health or welfare administration.

He also devotes a chapter to the relation of municipal health service to other official and unofficial health agencies as well as a chapter on hospital administration and hospital planning.

H. T. PECK

**PRACTICAL OTOTOLOGY** By MORRIS LEVINE, M.D. Octavo of 387 pages, with 145 illustrations. Philadelphia, Lea and Febiger, 1927. Cloth, \$5.50.

This book is a compilation of lectures given by Doctor Levine at the Post-Graduate Medical School and Hospital during the past twelve years. It is written in a very interesting manner and brings out all points of interest and information to the medical student, general practitioner as well as to the otologist. It embodies the experiences of a teacher and otologist. The relation of the ear to the general systemic condition of the patient is constantly kept in mind throughout the book.

This book is profusely illustrated with many helpful cuts and photographs. The anatomy of the structures is clearly put forth and the pathology of the various diseases is fully discussed.

This book will fill the needs of all students of otology and can be recommended as a reference book to the otologist.

SAMUEL ZWERLING

**EARLY DAYS OF THE PRESBYTERIAN HOSPITAL IN THE CITY OF NEW YORK**. By DAVID BRYSON DELAVAN, M.D. Octavo of 191 pages, with 34 illustrations. Published privately, 1926. East Orange, N. J., The Abbey Printshop, Inc., 1926. Cloth, \$1.50. (Copies may be obtained by applying to the Joint Administrative Board, 17 East 42nd Street, or to the Presbyterian Hospital in the City of New York, 41 East 70th Street.)

"Early Days of the Presbyterian Hospital in the City of New York" by Dr. David Bryson Delavan is a remarkable, brief account of the successful development of one of our finest hospital institutions from its infancy and even from its inception in the mind of that great philanthropist, James Lenox.

Dr. Delavan very concisely sketches for us the early struggles and the final attainment in the formation of training schools for nurses. He also shows us the contrast of the old time hospital methods of surgery and care of the patient and the nursing situation with the modern scientific methods.

His brief biographies of some of the old time pioneers of medicine in New York City are very interesting.

WM. RACHLIN

**A HANDBOOK OF DISEASES OF THE STOMACH** By STANLEY WYARD, M.D. Octavo of 387 pages. New York and London, Oxford University Press, 1927. Cloth, \$5.00. (Oxford Medical Publications.)

In this book of about 400 pages the author attempts to cover the entire subject of diseases of the stomach. The anatomy and physiology are among the first topics discussed and such a rare condition as Gastric Claudication is also considered.

Of many of the more important phases associated with the diagnosis of gastric diseases, such as X-ray, little is said. A discussion of Ulcer of the Stomach does not include that of Duodenal Ulcer, nor is any mention made of the latter condition. Such rare conditions as anthrax and actinomycosis are briefly mentioned.

This book has been written largely from the personal experience of the author, with only an occasional reference to the literature, and without any bibliography whatsoever.

It is a pleasure to note that a great deal of the old time-worn and impractical data has been excluded, but we feel that an attempt to cover the field in so short a treatise results in a condensation of a great many important conditions that should be dealt with at greater length.

IRVING GRAY

**THE CAUSE AND CURE OF SPEECH DISORDERS** A Text Book for Students and Teachers on Stuttering, Stammering and Voice Conditions. By JAMES SONNETT GREENE, M.D., and EMILIE J. WELLS, B.A. Octavo of 458 pages illustrated. New York, The Macmillan Company, 1927. Cloth, \$4.50.

This volume is really a digest of previous works along this line of affliction, with a great many original ideas injected into it.

The clearly defined differential diagnosis of the various types of disorders viz, stuttering, stammering and voice disorders places the treatment on a more common sense basis. The volume up to the chapters on treatment might be beneficially read by the laity as well as by the general medical practitioner.

There is all through the book, a warning signal to those, who treat this type of cases in a light manner. Great stress is put on the possibility of a psychosis developing in the neglected or carelessly treated cases.

According to the authors the stutterer is a defect of mental affliction and therefore must be treated from a psychic and psychological standpoint.

The peculiar psychic element that so often surrounds these sufferers makes the treatment rather complicated.

The Authors' outline of treatment and the careful history demanded, and undoubtedly necessary, make it so extensive that it really places the management of such patients beyond the possibility of the general practitioner.

In view of the psychosis which often prevails, a fairly good knowledge of psychiatry and the psychological insight of these sufferers must be possessed by the attendant.

# BOOK REVIEWS

**INTERNATIONAL CLINICS** Thirty-sixth Series 1926  
Volume 4 Octavo of 308 pages, illustrated. Philadelphia and London, J B Lippincott Company, 1926

One of the opening contributions in this issue is on diabetes when associated with acidosis, coma and infections. The author's advice is really quite unusual. He advises to give sugar in the presence of such a situation. He is quite unaware that diabetes mellitus is a quantitative disease, and gives advice for its management that anyone with the most limited experience must have found disastrous. The following articles cover a wide field, and have a varying degree of interest. Dr Black gives one the impression that it is quite unwise to fear myxedema after goiter operations, but it has happened often enough so that it is not quite unheard of. The internationalism of the issue is represented by articles from Holland, Germany, Austria, etc. The issue ends with a review of the 1926 meeting of the Interstate Postgraduate Assemblies of North America at Cleveland, where the present trend of thought concerning many problems of medicine is presented.

J ARTHUR BUCHANAN

**RECENT ADVANCES IN HAEMATOLOGY** By A PINEY, M D  
Octavo of 276 pages, illustrated. Philadelphia, P Blakiston's Son and Company, 1927 Cloth, \$3.50  
The little volume is part of a series of volumes known as the Recent Advances Series

The reviewer found it so interesting that he enjoyed reading every word of it. Among the numerous examples of medical literature which fall to the reviewer's lot, this work stands out very prominently. The subject of hæmatology is well covered from the standpoint of modern investigation. Much of the material presented is the result of original research and the conclusions are obviously founded upon deep and sound thought.

Although the medical profession may not be prepared to accept Dr Piney's theory of pernicious anemia, leukemia and allied conditions as due to a primal defect in the hæmatopoietic system his observations and deductions provide food for thought. The explanations offered, the descriptions given and the conclusions arrived at are presented in a clear, concise and enjoyable manner. It is certainly a work that no progressive physician can be without and should prove especially valuable to those interested in the vagaries of the hæmatopoietic structures and the results due to the pathologic conditions that arise from them.

MAX LEDERER

**A TEXT-BOOK OF MEDICINE.** By American Authors  
Edited by Russell L Cecil, A B, M D Octavo of 1500 pages, illustrated Philadelphia and London, W B Saunders Company, 1927 Cloth, \$9 00

This book comprises the contributions from 130 physicians whose work in their particular branches is authoritative. There are about 1500 pages of good solid reading matter with an excellent survey of general medicine and neurology. From a diagnostic and therapeutic standpoint this book can be highly recommended.

HENRY JOACHIM

**CYSTOSCOPY** A Theoretical and Practical Handbook  
Containing Chapters on Separate Renal Function and Pyelography By JAS B MACALPINE, F R C S 12mo of 284 pages, illustrated. New York, William Wood and Company, 1927 Cloth, \$7 00

This excellent book comprises almost three hundred pages devoted to all the phases of cystoscopy. The work is intended more particularly for the beginner or for the

occasional operator who has limited opportunity in this field. It should prove most helpful to any clinician in his earlier years of cystoscopic investigation. The work is fully and beautifully illustrated, and the colored plates are striking.

Macalpine has entered into much detail in technique, which is so essential to accurate diagnosis.

It is interesting to note that the English are still using the Nitze type of instrument. We believe, however, that the American type (Brown-Buerger) of instrument has many advantages over the Nitze, which are too numerous to mention here.

We also believe that the author's book is a real contribution to urologic diagnosis.

AUGUSTUS HARRIS

**THE NORMAL CHEST OF THE ADULT AND THE CHILD**  
Including Applied Anatomy, Applied Physiology, X-Ray and Physical Findings. By J A MYERS. In collaboration with S Marx White, and others. With an introduction by Elias P Lyon. Octavo of 419 pages, illustrated. Baltimore, The Williams and Wilkins Company, 1927 Cloth, \$5 00

It seems hardly necessary to state that accurate knowledge of the normal is essential to the recognition of the abnormal, yet, so frequently is the attention centered upon the abnormal that one omits the occasional review of the normal. With this thought in mind, the author of this volume has presented a study of the normal chest, developmentally, anatomically, neurologically and physiologically, he has given clearly the different procedures used in the examination of the respiratory and the circulatory systems, physical diagnosis by means of the normal chest of the adult and of the child has been instructively presented. For clearness of expression, thoroughness and simplicity of presentation, this is a wonderful study. The typography of the book is excellent, good paper, large print and good illustrations. This is one of the best books of the year, not only upon the subject of the chest, but also upon the subject of physical diagnosis of the lungs, heart and larger blood vessels.

HENRY M. MOSES

**ULTRA-VIOLET RADIATION AND ACTINOTHERAPY** By ELEANOR H RUSSELL M D, and W KERR RUSSELL, M D 2nd Edition. Octavo of 429 pages, illustrated. New York, William Wood and Company, 1927 Cloth, \$5 00

A very acceptable addition to the literature on light therapy. On comparison with the first edition of this work the present one shows many changes which bring it right up to date and add greatly to its interest and value. Among others there are very instructive chapters describing the older and the new ultra-violet generators and their respective properties. The historical and biological discussions are very interesting and thorough. The use of diathermy with light treatment is well presented, as is also the use of light in the specialties. The book is well illustrated and can be recommended as an excellent and authoritative treatment of its subject.

JEROME WEISS

**THE RELIGION CALLED BEHAVIORISM** By LOUIS BERMAN, M D 12mo of 153 pages, illustrated. New York, Boni and Liveright, 1927 Cloth, \$1 75

Any physician dealing with behavior disorders is interested in every phase of psychology. Of late, Behaviorism, as taught by Dr Watson, has arrested the attention of those dealing with behavior disorders. Not a few regarded this theory as a most fascinating one, and yet one which really is inapplicable in solving men-

## THE ST LOUIS TORNADO

The medical aspects of the tornado which struck St Louis on September 29, at 1 05 o'clock, are discussed in the November issue of the Journal of the Missouri State Medical Association in the following editorial

"Olive Street, thickly lined with small business houses, was filled with debris from ruined and damaged buildings, telegraph, telephone and electric light wires, and made impassable one minute after the storm struck it. On Olive at Sarah Street was a building containing the offices of a number of physicians. All these offices were wrecked and the physicians' equipment ruined but no lives lost.

"The Wall Building on Olive at Vandeventer, a six-story building entirely occupied by physicians and dentists, suffered no serious damage but the electric lights, elevators and the power for X-ray and other apparatus were destroyed and not restored for several days.

"In the northern part of the city the Mulanphy Hospital was completely wrecked but none of the sixty-three patients were injured. The hospital had to be abandoned and the patients distributed among other hospitals. The Deaconess Hospital at West Belle and Sarah was damaged to the extent of \$65,000 and the Shriners Hospital for Crippled Children, near Forest Park, was damaged to the extent of \$25,000. No persons were injured at either of these hospitals.

"None of the buildings along Grand Avenue occupied chiefly by physicians and dentists were damaged but the Beaumont Medical, Humboldt, University Club and Metropolitan buildings were all deprived of light and power for several days. The Missouri Theatre Building where the Association has its headquarters, is the only large building in the district that was not deprived of these facilities.

"The tornado struck the city with such suddenness and passed through with such rapidity that it was several hours before those who did not live in the damaged area were aware that any serious damage had been done. The hospitals, however, soon were made aware of the casualty when calls for ambulances flowed in and numerous automobiles brought injured persons needing attention. This brought the calamity to the attention of the physicians and through the quick organization of a relief force of the members of the St Louis Medical Society by the President, Dr C A Vosburgh, and the ready activity of the Red Cross, medical aid was almost immediately furnished. Tetanus antitoxin was supplied free to all injured persons and administered at all the hospitals and by the emergency physicians. Thus far no case of tetanus has developed although the nature of these injuries would make this danger a real problem."

## ORAL SEPSIS

The subject of focal infections in the mouth has been presented in medical journals frequently, but an especially practical article appears in the October issue of the *Kentucky Medical Journal* by Dr E C Rosenow, of Rochester, Minn. Dr Rosenow has done much experimental work on animals by the injection of cultures from infected foci in man, and has reproduced lesions, such as those of endocarditis, by the injections of cultures from joints of human heart patients. Concerning the elective localization of the infective germs Dr Rosenow says

"The best proof of the etiologic relationship of a focus of infection to a given lesion is the production of the lesion in animals with bacteria isolated from the focus in the patient.

"Through the use of special cultural methods

in which due consideration was given the question of oxygen tension and the injection of animals with the freshly isolated strains, extremely characteristic localizations were obtained with *Streptococcus viridans* from patients with subacute bacterial endocarditis, and with streptococci isolated from the joints of patients with rheumatic fever before the idea of elective localization occurred to me. The peculiar localizations obtained were considered due to different species of streptococci, rather than to peculiar temporary properties of different strains of the same species. It was not until ulcer of the stomach was produced in animals during my study on the transmutation of pneumococci and streptococci with "laboratory" strains that had attained

(Continued from page 1280)

a certain grade of virulence from successive passage through animals that the theory of elective localization took definite form. The long series of experiments in animals that have been performed since by myself, my pupils and independent workers leaves no doubt that the elective power of the bacteria in foci of infection largely determines the location of the systemic lesion or disease a person with foci of infection is likely to develop."

Discussing latent foci the author says

"In order to remove all doubt regarding the importance of latent foci of infection as an important factor in the production of disease, Meissner and I produced latent foci by devitalizing and infecting the teeth in dogs, thus closely simulating the conditions often inadvertently induced in persons by dentists. Nephritis, nephrolithiasis, ulcer of the stomach, spasms of the diaphragm and other muscles, and chorea have been produced in this way with culture isolated from patients with these respective diseases, and in each instance the causal relationship of the organism introduced into the teeth to the metastatic lesion has been established by the demonstration of the organism in the lesions and focus and by the elective localizing power of the strains isolated. During the latter experiments, another important fact was noted. The bacteria in the induced latent focus of infection, besides producing the characteristic disease, appeared to exert general deleterious effects. The animals lost weight and became more susceptible to intercurrent infections, although they were kept under conditions identical with those of control animals. In other words, conditions of hygiene and diet that were adequate to maintain weight and health in normal dogs were inadequate for dogs with latent foci of infection. The harm, therefore, from improper food or sanitation may be greatly exaggerated by bacteria harbored in foci of infection, a point not yet sufficiently considered.

"The fact that bacteria of the same species localize electively, depending on the degree of virulence or other acquired property, is no more remarkable than the fact that bacteria of different species tend to localize in particular organs or tissues. The loss of virulence of streptococci or other bacteria on artificial cultivation and its increase on passage through animals are well recognized. The change in localizing power likely occurs for the same reason.

"The reasons for the elective localization of bacteria are still obscure. No doubt the same principles that determine the localization or pharmacologic action of the chemicals and drugs apply here. Indeed, my experiments in ulcer of the stomach and epidemic hiccup strongly support this hypothesis. It was found that strains of the

(Continued on page 1283, adv xv)

(Continued from page 1282, adv xv)

streptococci from patients with ulcer which had elective affinity for the mucous membranes of the stomach and which produced ulcer, on intravenous injections elaborated a poison of toxin within the bacterial cell and in the broth that had specific damaging effects. Injection of the washed dead bacteria and filtrates of actively growing cultures produced hemorrhage and ulcer of the stomach without inciting lesions elsewhere. Even more striking were the results following intracerebral injection of living cultures of the streptococcus from patients with epidemic hiccups, the dead bacteria, and filtrates of freshly isolated cultures. In each instance, spasm of the diaphragm or other muscles was produced. Moreover, filtrates of nasopharyngeal washings and pus from tonsils at the time of attacks sufficed to provoke spasms, whereas, similarly prepared filtrates, after recovery, were without effect."

The author says, in discussing the practical applications of the principles of focal infections.

"The practical applications of the principles of focal infection and elective localization are fraught with many difficulties. Systemic diseases, once thoroughly established and often associated with anatomic changes that in themselves may continue to give rise to symptoms even though there are no organisms present, may continue after all evident foci are removed. The instances of cure or arrest of progress in systemic diseases by the removal of foci of infection are so numerous that search for and removal of all foci possible is indicated in almost every case of serious systemic disease in which there is good clinical or experimental evidence of focal origin. In a given case the variations in the invasive power of the bacteria, the wide differences in natural or acquired resistance to microbe invasion in different persons and at different times, the age and sex, the history of previous attacks, the duration and character of the disease from which relief is sought, and hereditary tendencies must all be considered in determining when, or whether, all or certain foci should be removed, or whether the condition is indeed of focal origin.

"Infections of the dental pulp, pulpless teeth and apical abscesses are theoretically the most dangerous of the various forms of dental foci. They are usually free from symptoms and hence unsuspected. They are situated in osseous tissues which allow no expansion. They can drain only into the circulation and are exposed to pressure transmitted by the teeth during mastication. They remain active for years, and the bacteria are not encapsulated, as is usually assumed, but are found in areas of active inflammatory reaction where the formation of new blood vessels affords drainage into the circulation."

## PREVENTIVE MEDICINE

The October issue of the West Virginia Medical Journal quotes the following editorial from the *Baltimore Sun*:

"Once upon a time you called a doctor when you were sick. Then came the idea of preventive medicine, which in recent times has grown by leaps and bounds. It has done more than could have been accomplished by a 'Use More Doctors' week. We no longer wait to be sick. We go to the doctor to keep from getting sick.

(Continued on page 1285, adv xvii)

(Continued from page 1284, adv xvi)

He vaccinates us against smallpox, sticks us for typhoid and again for diphtheria. If we have chronic colds, he may treat the colds but he prefers to take out our tonsils and adenoids, preventive measures against all sorts of ills, from lassitude to laryngitis. No telling what a mole may come to. Have it off. You may be in a bad way and not know it. Have a thorough physical examination and extend your life.

"Is a child bow-legged or knock-kneed, are its teeth crooked, has it a cast in the eye? These things were once regarded as acts of Providence and therefore to be left alone. Today we are led to believe that they can be corrected and that if neglected they may cause all sorts of troubles in years to come from headaches to loss of opportunity to wed. No parent who has the true interest of a child at heart can turn a deaf ear to the dentist, the orthopedist and the optician, and another specialist must be called in to determine what the child shall eat.

"In the old days an ounce of prevention was said to be worth a pound of cure. Today we have a pound of prevention for every ounce of cure. Preventive medicine was once a luxury to be indulged in only by the wealthy. Today it is as much a part of the average up-to-date home as an electric range, an electric refrigerator, a telephone and an automobile.

"Preventive medicine, if it has not been the cause, has accompanied the transition of the family from a system of extensive culture to one of intensive culture. The family acreage has been cut down to permit of more tilling and fertilizing.

"No one would dare to question the virtue of preventive medicine any more than he would question the other improvements of modern civilization. But like most modern improvements, it makes a dent in the pocketbook."

### FLY LARVÆ IN THE INTESTINES

The larvæ of two-winged insects, or flies as they are commonly called, may occasionally be found in the intestine of man and may produce a gastro-intestinal disturbance, but seldom a serious disease. The condition is called myiasis from the Greek word, *myia*, a fly.

The October number of the Journal of the Arkansas Medical Society contains an article on intestinal myiasis by Dr. A. A. Blair describing the case of a man who had an itching of the rectum and a mild diarrhoea. In his stools were a large number of maggots which were small, white and pointed. The larvæ would disappear and recur at intervals all summer. The larvæ were finally identified as those of a fly, *sarcophaga hemorrhoidalis*, which lays its eggs in berries.

A place where your patients can find attractive surroundings with adequate medical service and supervision.

Logan Clendening in his recent classic 'Modern Methods of Treatment' says, 'The benefits to be derived from a Cure at a Mineral Springs depend, almost entirely upon the efficiency of the medical organization thereat.' This principle has always been and still is the one which has so largely contributed to the deserved fame of the French Lick Springs Hotel at French Lick, Ind. When your patients are tired of home or hospital, send them to us for final recuperation. Through Pullman Service, New York to French Lick via Pennsylvania R. R.

(Continued from page 1285, adv xvi)

The man gave a history of eating quantities of berries freshly picked

Dr H Thibault, in discussing the paper, said that patients sometimes complained of maggots in their stools when the larvæ were those of viviparous fly which placed them on the stool after its exit from the person's body

The doctor also suggested a method of identifying the larvæ Place a part of the stools in an ordinary fruit jar with some earth in which the larvæ may pupate When the adult flies emerge they may easily be identified

## PRIVATE PRACTICE AND PUBLIC HEALTH

The responsibility of the medical profession in public health organization was discussed at the Sixtieth Annual Meeting of the West Virginia State Medical Association on June 21, 1927, by Dr J E Monger, State Health Commissioner of Ohio His paper was published in the November issue of the West Virginia Medical Journal from which the following abstract was taken

"Public health is the application of the principles of preventive medicine to control the community problem of disease The physician's problem is the problem of his individual patient's diseases and welfare, and the public health man's problem is that of community disease and community welfare

"It is entirely impossible to disassociate community disease and community welfare, and individual health and individual welfare, for after all the community's welfare is dependent on the presence or absence of disease in individuals In other words, the health officer tries to do for the community what the doctor tries to do for the individual

"We physicians have long been looking at the Public Health Movement, and I am quite sure that many of us do not see its whole purpose

'First of all, the Public Health Movement is relatively new And second, most of us received our training at such a time and under such circumstances that we come naturally to regard our life-mission as one of treating diseases, and not of preventing them

"The accomplishment of the organized fight against tuberculosis, the marvelous results obtained when a minimum of effort was expended toward the reduction of infant mortality, the reduction of blindness through organized effort,—these are only a few of the many achievements that taught society that disease prevention was not alone the business of the doctor, but was the business of society in general

"It is not unusual to find that public demand for preventive measures is far in advance of professional acquiescence to their application

(Continued on page 1287, adv xix)

(Continued from page 1286, adv xviii)

Let me illustrate what I mean by a concrete example"

The author goes on to describe a campaign in a small Ohio city in which the children were examined and their defects were corrected, and on May Day a big parade was held in which 3,600 blue ribbon children (those free from defects) paraded. He then says

"This year at a dinner given on the occasion of the community celebration of a bigger and greater demonstration, the Mayor in a public address to assembled health officials made this statement.

"This thing has been popular, immensely popular, with everybody and with every class of citizen but one, and I am sorry to say that class is the medical profession. They look on it with doubt, and are consistently objecting

"I see wherein they are wrong, and while I want their support, still if I cannot get it, I intend to give local public health administration our full official support because I believe it to be the most important factor working for a healthy community today and a better community in the future"

Dr Monger described the need that public health should have the support of the medical profession and said "We decided that the best way to sell public health to the doctor was to do the fair, just and equitable thing by him, and not do very much talking about it" The result was the loss of some support of voluntary agencies without a compensating gain from the support of physicians. However, the author is optimistic as to the response of physicians that they engage in public health work. There is a demand by the people that physicians protect them from diseases, and the author argues

"When people realize that diphtheria, scarlet fever, typhoid and smallpox are largely preventable, and they are not being prevented, they will ask somebody 'How come?' And that 'somebody' will be we doctors. We have arrogated this thing to ourselves, and we will be held responsible

"Let them know—and they are rapidly finding out—that the tragic deaths from heart disease, the tremendous toll of nephritis, is due largely to conditions that could have been prevented by the simple protective measures that could have been taken care of in childhood, and 'somebody' must answer many pointed questions"

Dr Monger illustrated his point by describing a young doctor who took over the practice of an older doctor, and after seven years he said

"I am going to leave here. There are not the opportunities here that there were in the old days. When you were in practice here you counted on about so many cases of typhoid each

## SALIPYRIN "Riedel"

is a chemical combination of antipyrin and salicylic acid. The therapeutic effects of both these components are preserved, although 'modified' by close chemical union and in a very great degree deprived of the dangers of mechanical mixtures.

Salipyrin is distinguished from other salicylates by the comparative

freedom from ill-effects (absence of free antipyrin) and prompt antipyretic and sedative action.

**INDICATIONS** Influenza, Colds, Catarrh of the Nose and Throat, Rheumatism, Neuralgia, Alcoholic Excess, Pleurisy, Dysmenorrhea, Metrorrhagia, Vaginitis, etc. If given early in the attack, Salipyrin generally succeeds in aborting colds.

Salipyrin is supplied in powder form and as SALIPYRETS in tablets of 7½ each

Approved by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion with N. N. R.

**RIEDEL & CO., Inc.**

Berry and South 5th Streets, Brooklyn, N. Y.

(Continued from page 1287, adv xix)

fall, you were busy with diphtheria, tonsillitis and rheumatism in the winter and spring, and in the summer dysentery and enteritis kept you employed. I haven't seen a case of typhoid in eight years. Diphtheria only means two or three visits. I have taken out nearly all the kids' tonsils and they don't have tonsillitis. I have cleaned up focal infections and bad teeth, and seldom see a case of rheumatism. Dysentery is unknown, and only an occasional attack of diarrhea and enteritis. In fact, over 70 per cent of the work you did is now non-existent."

The author then described the rest of the interview.

"Do you do any immunizing against typhoid?" His answer was 'No'. 'Are you Schick testing and immunizing against diphtheria?' 'No'. 'Are you doing pre-natal supervision of prospective mothers?' Again, 'No'. 'Are you doing real, honest-to-goodness pediatric work and supervising your well babies?' Again, 'No'. 'Are you doing any examination of well people and furnishing them with supervisory service?' Again, 'No'. 'Are your school children being sent to you for correction?' 'No'.

"All through the category of public health and preventive medicine he was not realizing a dollar. Finally he became impatient, and rather testily pointed out that while he realized that all this should be done, that he could not educate the

people to have it done and be willing to pay for it. And right there I nailed him! This county had indifferent public health service, with an aged physician as health officer, and one nurse for 800 square miles, and 35,000 people.

"I pointed out to him that a good, well-functioning health department would teach prospective mothers the value of pre-natal supervision and supervision of early infancy, the importance of physical examination of well people, the value of correction of defects, the importance of immunization against typhoid, smallpox and diphtheria.

"I convinced him that there are today more potentialities for service in that community than there were fifteen years ago, and that people are better able and more willing to pay for such a service.

"Well, how can this be brought about?" "Easily," was my answer. "Get yourself and some other physicians with vision appointed on your board of health, and see that progressive laymen are also appointed."

Of course the story ends well, with the young doctor as Chairman of an efficient County Board of Health.

Dr. Monger sums up his creed in the following sentences:

"As a health officer I know that I cannot render my best service without the co-operation, help, and support of the doctor."

## VACATION IMPRESSIONS

The editor of the *Rhode Island Medical Journal* gives editorial expression to his thoughts regarding vacations in the October issue. The advice is good, and the editor evidently took some of his own medicine which must have worked well or else he would not be recommending it to others—*Editor's note*

"Presumably all wise physicians have taken a summer vacation. Some of us have in the past gone on the assumption that if we enjoyed our work we could work all the time and needed no vacation, but those of us in Rhode Island have seen some tragic examples of the fallacy of this idea, and know that a respite from our work and from contact with sick folks brings us back to our task better able to do good work. In addition to this general release from the pressure of work, we should on our vacation meet new friends, see new places and have some time for calm contemplation of a philosophy of life.

"As one visits various parts of New England or neighboring states and countries, one finds the road filled with automobiles dashing here and there, some of these automobiles, to be sure, are going to camps and beaches where their occupants will settle down for real relaxation, but the general impression gained is that this age of hurry is leading people to dash madly about, boast of the miles covered and all the different places visited. On a trip to Maine, the writer left a town in northern Maine at the same time a buckboard drawn by two horses left, the automobile and the buckboard had the same destination, it took the automobile two and one-half hours to make the trip—it took the horses two and one-half days to make the trip. One could not

help but wonder whether the modern age, with its rapid transportation, with its running on schedule and its general wear and tear, did not involve certain dangers to our nervous systems, as well as our digestive systems, that made the older method of traveling have many compensations. As one got away from the beaten tracks into the heart of the woods and looked out upon mountains and lakes in their calm majesty, a certain restoration of viewpoint was gained, and the peace and quiet of nature seemed to allay the hurry and worry of our modern life. Would not the physician do well to teach his patients the value of simple things, the dangers of speed, and the wisdom of a close contact with nature? If we are to continue to add years to the span of life, to gain a better sense of values and to maintain the best degree of health, isn't it time for us to align ourselves with the forces that teach a more sane living and an appreciation of the lessons provided all about us in the repose of mountains, lakes and rivers? Then, perhaps, we can do away with some of our sleeping potions, some of our digestive mixtures, and realize that we are surrounded with the healing forces of nature if we will only avail ourselves of them."

With what the Rhode Island editor says about vacations physicians will heartily agree. However, what doctors need is not so much one long vacation once a year, but a number of brief periods of relaxation every week, such as those spent in meetings of medical societies. One of the best of all vacations for a busy doctor is an evening with his fellows—a social supper, a cigar, and a scientific paper a half hour in length. A doctor will come from such a meeting at peace with himself and with his medical brethren.

## THE LEPRA HOSPITAL IN BERGEN, NORWAY

Leprosy is still a fairly common disease in some parts of the world. The *Kentucky Medical Journal* for September, contains the following account of a lepra hospital in Bergen, Norway, by Dr A. O. Pfingst, of Louisville, who visited the hospital.

"The hospital in Bergen is quite a good-sized, two-story frame structure, built in a square surrounding a beautiful court of flower beds, evergreens and lawn. It is well equipped with pathological and bacteriological laboratories, operating and dressing rooms, a large library, private apartments for the medical staff and for the nurses, bath equipment, etc. The rooms are large and airy, some facing the court and others overlooking a surrounding park. Two or three patients occupy a room. Everything about the place is immaculately clean.

"One could not but be impressed with the present status of leprosy and its management. When we see present conditions where leprosy patients are kept under cheerful surroundings and are attended by a trained staff of physicians and nurses and compare this to conditions as they formerly existed the value of segregation becomes apparent.

"There are over 100 patients in the Bergen hospital, the cutaneous and nervous types being about equally divided. With the one exception of a maniacal patient, who was kept in a padded cell, the patients seemed uniformly cheerful, notwithstanding their knowledge of the hopeless nature of the disease they harbor. The patients were allowed to intermingle in the court, at church service and during meals, but were naturally not allowed to leave the confines of the institution. Upon inquiry the director advised me that the danger of propagation of the disease is very slight as long as the proper rules of asepsis and hygiene are observed. He expressed the belief that closeness

## Vegex Concentrated Yeast Extract

Strongest and most palatable form of yeast for health, fermentation removed

Richest known source of B vitamins

Meat-like flavor, no meat, tasty, instant bouillon, broth, etc.

Adds vitamin B, iron and growth-promoting proteins in child feeding, expectant and nursing mothers

VEGEX is used by physicians in arranging diets in gastro-intestinal, diabetic and nervous disorders, post-operative cases, liquid diet in general practice

VEGEX is the physicians dependable source of the B vitamins and contains Dr Goldberger's "P-P" factor

VEGEX is accepted for advertising in the *Journal of the American Medical Association*

of contact bears a direct relationship with contagion and hence patients are not allowed to sleep two in a bed, to shake hands, or otherwise come in contact with each other. In his experience of 33 years, the doctor recalled but a single case a nurse, who had contracted the disease while at the institution.

"In Bergen the patients are visited by the medical staff twice a day. They are treated expectantly—necrosed bone removed, heavy layers of horny skin cut off and other symptoms relieved as they arise. No internal treatment is employed unless otherwise indicated. Chaulmoogra oil, of which so much was expected, is no longer used at Bergen as no results have been obtained from its use.

"I was struck at once by the large proportion of eye affections among the patients in the Bergen institution. It seems that this frequency of eye affections is common to all lepers, two-thirds to three-fourths of all cases having some form of eye complication and from fifteen to thirty per cent terminating in blindness. I was also impressed by the frequency of facial paralysis. It appeared as though every second or third patient had a unilateral facial immobility. Naturally, these patients were especially prone to eye complications."

"The cornea was frequently involved, showing a peculiar infiltration resembling parenchymatous keratitis. Students of leprosy refer to these cases as "Leprous Keratitis." They run an acute course with conjunctival redness and involvement of the uveal tract and leave a dense cloud in the cornea that at first appearance impresses one as a leucoma, the result of a healed ulcer. Several corneae were marked by punctate opacities rather than the diffuse clouds. Cornel ulcer is not so common, although it occurs especially in the patients with facial paralysis and at times leads to perforation and destruction of the eye."

## CHEMOTHERAPY IN DISEASES OF THE SKIN\*

By PAUL E BECHET, M.D., NEW YORK, N Y

THE field covered by the title is so vast, and the time so limited that it might be well, in this paper, to consider only that definition of chemotherapy which embraces the introduction into the blood stream of one or more chemical substances of a definite nature. Probably the earliest references to the use of chemicals and metals in medicine are derived from the works of that half charlatan, half scientist, Paracelsus. Cumston<sup>1</sup> records that Paracelsus collected all the discoveries scattered through the works of Geber, Lulle, Rhases, and Valentine, and by applying them to the treatment of diseases was literally the founder of chemotherapy. Among his favorite metals, we find gold for paralysis, fevers, and uterine pains, silver, for pain of cerebral, hepatic, or splenic origin, tin, for worms, copper, for ulcerations of the mouth, and mercury and lead for syphilis. He was, therefore, the first to establish the infallibility of mercury in syphilis.

From the astrologer and alchemist to the modern scientist, Ehrlich, little if any progress has been made. It remained for the latter, therefore, in his famous "Die Experimentelle Chemo-Therapie der Spirrillosen," in collaboration with Hata, to announce to the world the discovery of salvarsan. Since that time, medical literature has been bewilderingly filled with articles on the intravenous injection of dozens of synthetic and other chemicals, in various dermatoses. So great is the list that it might well remain within the bounds of reason that some important agent may be omitted from consideration in this paper.

The disease most affected by the intravenous use of chemical agents, and of course the most important, is syphilis. I shall, of course, make no mention of that remarkable triumvirate of specifics—arsphenamin, neo-arsphenamin, and silver arsphenamin. Their actions and results are too well known to an audience of this character. I will only state in passing that I never note their remarkable therapeutic action in syphilis without a feeling of gratitude to the

men whose brains and hands have made them possible. There have been, however, in the past few years, a considerable number of newer arsenicals which have been tried with more or less success. In this group belongs sulpharsphenamin. It is prepared by treating arsphenamin with formaldehyde and sodium bisulphite. Raiziss, Severac, and Moetsch<sup>2</sup> found that it was about one-half as effective as neo-arsphenamin in trypanocidal tests, and that it was also inferior to salvarsan. It has, however, certain advantages: it is much less oxidizable than neo-arsphenamin, and it is much less painful by intra-muscular injection. Stokes and Behn<sup>3</sup> considered it as efficient in therapeutic effect as arsphenamin and neo-arsphenamin. This drug has been used mostly by intra-muscular injection in patients unable to receive arsphenamin or neo-arsphenamin intravenously because of lack of veins. Lautman,<sup>4</sup> however, has administered more than four hundred doses of sulpharsphenamin intravenously to eighty-three patients. His technique was simplicity itself; he dissolved the drug in 30 cc of distilled water. It was readily soluble and caused but slight irritation if the solution leaked into the subcutaneous tissue. In no case was thrombosis noted. The first dose was 0.4 gm, the subsequent doses were 0.6 gm, and the injections were given every fourth day. His results were fully as good as with the older arsenicals. In his series of cases there were twenty-four with neuro-syphilis. In this group his experience coincided with that of others in concluding that in neural syphilis sulpharsphenamin seems superior to arsphenamin and neo-arsphenamin. None of the patients developed any skin disturbance, and only three had slight gastro-intestinal disturbances, which quickly subsided within a few hours.

Stovarsol, a pentavalent arsenical compound, the chemical name of which is 3 acetyl-amino-4-hydroxy-phenylarsonic acid, introduced by Tourneau, Levaditi, and Novarro-Martin<sup>5</sup>, and studied by Raiziss and Gavron,<sup>6</sup> has not as yet proven sufficiently valuable to even compare

\* Read at the Annual Meeting of the Medical Society of the State of New York, at Niagara Falls, N Y, May 11, 1927.

**BRAUN'S SNARTOME**

Tonsillectomy may be a minor surgery, but it requires its men to cope with it and the instrument to perform it.

It is only a few years since Dr Braun's tonsillotome was given to the profession, but its merits are daily realized.

Combining the slider and the snare method, it incorporates the advantages of both with none of the faults no hemorrhage, no trauma, applicability of the instrument to every type of tonsil—simple and easy technique are essential enough not to be overlooked. Sold by E B Meyrowitz Surgical Instruments Co., Inc., New York, N Y. See advertisement, page xvi—Adv

**LARCHMONT GABLES**—The pride of Larchmont—Doctor's suite on ground floor. No practicing physician in this large, fully occupied apartment house as yet. Overlooking the Sound in the center of a high class residential section. Apply to **HARRY RICH MOONEY**, Larchmont Gables. Phone Larchmont 1300

**PHYSICIAN WANTED**

The sudden death of a physician leaves vacant a splendid practice in prosperous community. Fully equipped office, reception room and bedroom for rent. Thorough introduction \$8,000 annually. Man with some experience preferred. Address N Y STATE JOURNAL, Box 97

**FOR SALE**—Established sanitarium in famous Long Island pine belt. 100 feet above sea level. One hour from New York City. Institution made present owner independent. For details write P O Box 62 Bay Shore, Long Island

**CLASSIFIED  
ADVERTISEMENTS**

Classified ads. are payable in advance. To avoid delay in publishing, remit with order. Price for 40 words or less, 1 insertion, \$1 50, three cents each for additional words.

**WANTED**—Salaried appointments for Class A physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nationwide connections enable us to give superior service. **Aznoe's National Physicians' Exchange**, 30 North Michigan, Chicago. Est. 1895. Member the Chicago Association of Commerce.

**Medical Periodicals, Back Issues**—We have for sale complete files, odd volumes and single copies of current and older issues. Books on the History of Medicine. We buy scientific magazines. **B Login & Son**, 29 East 21st St., New York, N Y

**DR. BELL'S PRIVATE REST HOME, SITUATED IN "THE QUEEN VILLAGE OF ONEIDA COUNTY"**

Doctor—Here is where your aged, chronic invalid or convalescent patient can receive medical attention and nursing, and still remain in the home atmosphere, still keeping entirely free from all sanatorium surroundings. Fees, payable in advance \$35 00 and up per week for double room, \$70 00 and up per week for single room, said fees covering board nursing and medical care. Address **H WALSWORTH BELL, M D** Camden Oneida County New York

**SCHOOL OF VOICE HYGIENE**

Devoted to treatment of defective voice and speech disorders. Stuttering, stammering, lisp, hoarseness—courses given. **John Levborg, M D** (Steinway Hall—1611) 113 West 57th Street, New York. Circle 0593—Lehigh 2460. By appointment only

31 Park Avenue. Choice of two private of fices. Ideally located private dwelling. Living quarters if desired. Also opportunity to secure hours in completely equipped office. Full service. Unusually inexpensive. Telephone Caledonia 7218

**VITAMINS**

The Vitamin Food Company is pioneering the sale of vitamin-rich yeast foods and tasteless cod liver oil concentrates of high vitamin potency. Their principal executives, consisting of a physician and a former food commissioner of one of the States, have stated the dividing line between vitamin products for food and their use in medicine in two typical letters

**TO A MOTHER IN NASHVILLE**

"**VEGEX** is used with nursing infants and children as well as grown-ups to supplement milk with vitamin B, iron and growth promoting proteins. You can use it just as you would milk and oranges. It is a food, not a medicine

"But you state that your baby is underweight. In this, you should immediately consult your family physician and, if necessary, have him recommend one of the excellent physicians in Nashville who specializes in the feeding and care of children. Only the physician can accurately find out what is the matter. The Science of Medicine now has excellent methods for accurate diagnosis

"Your physician will tell you that the vitamins and other constituents in **VEGEX** are necessary for child growth, but he will also tell you the other things that your child may need"—Adv

**University of Buffalo School of Medicine**

Requirements for admission: Two years of college work, including twelve semester hours of chemistry, eight semester hours each of physics and biology, six semester hours of English, and a modern foreign language.

Laboratories fully equipped. Ample facilities for the personal study of cases.

Address: **SECRETARY, 24 HIGH STREET, BUFFALO N Y**

*57 Advertisers have taken space in this issue of your Journal. Give them your business when possible.*

Syracuse, N Y., Nov. 15, 1927

Dear Doctor:

Have you sent for one of our Catalogues?

We manufacture a large variety of products, and stock nearly everything a dispensing physician needs.

Our prices will represent a large saving on your purchases

**MUTUAL PHARMACAL CO., Inc.**

The most important recent achievement in the treatment of dermatoses by means of chemotherapy is the use of gold in lupus erythematosus. A gold compound, 4-amino-2-aurothiophenol-carbonic acid, under the name of "Krysolgan," has been used extensively in Germany, Ruete<sup>26</sup> reporting complete healing of an acute lupus erythematosus after seven injections of the compound. Martenstein<sup>28</sup> used Krysolgan in the treatment of forty-two patients, with cure in twenty-eight, and improvement in six. Favorable results with Krysolgan were also reported by Fried<sup>27</sup> and Ullmann.<sup>28</sup> Schamberg and Wright<sup>29</sup> used gold and sodium thiosulphate in twenty-four patients suffering from lupus erythematosus, with the following results: disappearance of lesions in five cases, practically well, six cases, improvement in twelve cases (a number still under treatment). Only one patient showed no improvement. The gold and sodium thiosulphate they use has the formula  $\text{Na}_4\text{Au}(\text{S}_2\text{O}_3)_2 \cdot 2\text{H}_2\text{O}$ . It is quite stable in the dry state, readily soluble in water, and contains 37 per cent of gold. I have used this preparation in thirty cases of lupus erythematosus discoides, one case of lupus erythematosus disseminatus, one case of lupus vulgaris, one lupus pernio, one lupus miliaris disseminatus faciei, two papulo-necrotic tuberculids, and three erythema induratum. Of the thirty cases of lupus erythematosus discoides, four showed complete disappearance of the eruption, four were practically well, eleven were greatly improved, ten were slightly improved, and only one showed no improvement. The last had considerable local reaction, with a generalized vesicular eruption after the seventh injection, and did not return for further observation. The lupus pernio showed no change after five injections. The lupus vulgaris also showed no improvement after eight injections. The disseminate milium lupus vulgaris was extremely extensive. There was rapid improvement after three or four injections, and apparent complete cure after fourteen injections. One of the cases of erythema induratum also had a papulo-necrotic tubercloid of the hands. She received twenty injections in four months. The eruption was entirely cured. Another case of erythema induratum had received sixteen tuberculin injections without benefit, yet after twelve injections of gold and sodium thiosulphate she was nearly well. The third case of erythema induratum showed marked improvement after four injections. Another gold preparation, Triphal, has been used extensively with exceedingly good results.

Within the past eight months, numbers of cases have been exhibited in New York by Wise, MacKee, Rosen, Clark, Fraser, Throne, and others, with evidences of marked improve-

ment, and even apparent cure from the use of gold.

A simple but important remedy in the treatment of bromoderma, namely, the intravenous injection of 100 to 500 cc of decinormal saline solution, was first called to our attention by Wile.<sup>30</sup> He used the method in three cases, with rapid disappearance of the lesions. The author<sup>31</sup> also had equally good results in three cases, one of which had resisted other treatment for months. MacKee, at a recent meeting of the New York Dermatological Society, showed a case of bromoderma in an epileptic, where the oral administration of salt kept the lesions in check, thereby enabling the patient to continue his bromide therapy.

Young, Hill, and Denny<sup>32</sup> used intravenously mercurochrome-220 soluble in twenty-four cases of erysipelas. The results obtained were remarkable, although several had been almost moribund. Furunculosis also responded, of eleven cases treated, ten were cured and one improved.

Maloney<sup>33</sup> used sodium salicylate intravenously in twenty cases of psoriasis, with no lasting improvement in any case, the lesions recurring shortly after cessation of treatment. Smith<sup>34</sup> also had a high percentage of failures, 52 per cent.

Wolf<sup>35</sup> injected five cc of a ten per cent solution of sodium bromide in ten cases of eczema and other itching dermatoses. The itching was often relieved by a single injection. The most striking benefit was in a case of chronic senile pruritus in a man of eighty-six.

Throne, Van Dyck, Marples, and Myers<sup>36</sup> have used sodium thiosulphate intravenously in eczema of arsenical origin, with great benefit.

Pijper<sup>37</sup> in 1918, introduced into South Africa the use of arsphenamin in the treatment of anthrax, and has used the method in forty cases without a single death. Grasser<sup>38</sup> used arsphenamin in fifty-four cases of anthrax with remarkably good results. In mild cases, a single injection of 0.45 to 0.6 grams was frequently found sufficient.

Antimony and potassium tartrate is now properly considered to be a specific in granuloma inguinale. Fox<sup>39</sup> collated 150 American cases in which the drug was used. In seventy-eight complete healing took place, and in thirty-one there were various degrees of improvement.

Tartar emetic has also been used intravenously in a 2 per cent solution in leprosy, with very favorable results. Cawstein<sup>40</sup> particularly noted its good effects in ulcerating leprous lesions.

Comment. Bismuth, mercochel, and sulpharsphenamin in all stages of syphilis, tryparsamide in neuro-syphilis, sodium thiosulphate in metallic intoxications, and gold and sodium

with the arsphenamins, even though it is much in use in Germany and Vienna

Another arsenical pentavalent compound, tryparsamide, the sodium salt of N-phenylglycineamide-4-arsonic acid, discovered by Jacobs and Heidelberger,<sup>7</sup> has been found to be of some value in neuro-syphilis by Raiziss, Severac, and Moetsch.<sup>8</sup> Lorenz, Loewenhardt, Blackwenn, and Hodges,<sup>9</sup> state that marked improvement has been noted both serologically and clinically in all stages of paresis. Some patients become mentally normal after the intravenous injection of three to five grams. According to Raiziss, it must be used cautiously, as it has a deleterious effect on the optic nerve. He states, however, that this defect might be overcome by careful regulation of the dosage. Stokes and Wilhelm<sup>10</sup> found that tryparsamide was not suited to the treatment of early syphilis, and was in no sense a substitute for the arsphenamins, yet in neuro-syphilis of the resistant type it was superior, both serologically and clinically. Eye complications constituted a definite risk.

In 1919, Linser<sup>11</sup> advocated the combined use of mercury and salvarsan, using a mixture of 0.45 to 0.6 grams of neo-arsphenamin and 0.02 to 0.04 grams of sublimate. Ten to twelve injections were made at intervals of three to four days. Results were uniformly good. This work was followed by Bruck, Holzhauser, Kolle, Schmidt, Brann, and Blumener, who used various combinations of mercury and salvarsan, also with good results. Schamberg<sup>12</sup> sounds a word of warning, he found that vigorous mercurial treatment was often responsible for arsenical intoxication, and states that they should not be used jointly. The courses of mercury are best given subsequently to the arsenic, and in this opinion the majority of American syphilologists concur.

On the basis of the work of Ravaut of France, in 1920, and McBride and Dennie in this country, in 1923, it is now known that arsenic, mercury, and other heavy metals can be transformed into soluble compounds by the intravenous injection of sodium thiosulphate in increasing doses. It is therefore of great help in arsphenamin dermatitis and mercurial stomatitis and diarrhoea. Several syphilologists are now using sodium thiosulphate in conjunction with the arsphenamins as a preventive of arsenical intoxication in susceptible individuals.

Bismuth compounds, as antisyphilitic remedies, have made their appearance in the past six years. Sazerac and Levaditi<sup>13</sup> first used bismuth in rabbit syphilis with remarkable results. They immediately began the treatment of human syphilis, with exactly similar good results. Fournier and Guenot, Müller, Chevalier, Nicolas, Massia and Gaté, Jeanseime,

Millan, Pomaret, Louste, Tibaut, and Barbier, are among the most enthusiastic European observers. Bismuth seems particularly effective in arsenic-resistant and latent syphilis. McCafferty<sup>14</sup> found it as effective as arsphenamin. Raiziss believes it to be more effective than mercury. Hopkins<sup>15</sup> believes that it should be included in the routine treatment of syphilis. Schwartz and Levin<sup>16</sup> state that it has more spirochetal value than mercury. Sutton<sup>17</sup> states that its intravenous injection is to be strictly avoided, yet Lacapere and Galliot<sup>18</sup> used a colloidal bismuth suspension in a series of from twenty to twenty-five intravenous injections at the rate of three a week, in thirty cases with excellent results, the drug being well borne. Stomatitis seemed much less frequent than after the intramuscular method. A German colloidal bismuth preparation, called bismuth diasporal, has been used intravenously by Curt Schmidt, Portmann, Lenzmann, and Hubner, with apparently no deleterious effect.

Of the newer preparations of mercury, Fluimerin, prepared in this country by White, Hill, Moore, and Young<sup>19</sup> is recommended for intravenous injection. It is the disodium salt of hydroxymercuri-fluorescin. White and his collaborators thought it of sufficient value in syphilis to warrant further use. Moore and Wassermann<sup>20</sup> found it markedly inferior to arsphenamin. Fox, Gildersleeve, and Preston<sup>21</sup> gave 185 injections to a series of twenty-four patients over a period of eighteen months. They found that it had a fairly accurate spirochetal value and that it caused rapid regression of secondary lesions.

Mercurosal, a derivative of salicyl-oxy-acetic acid and mercury acetate, the chemical name of which is disodium mercuri salicyl-oxy-acetate, was used by Cole, Driver, and Hutton<sup>22</sup> in thirty-eight patients with syphilis. Many showed marked improvement, but a summary of the results with this drug did not show any superiority over the better known mercurials. On the other hand, Williams<sup>23</sup> considered it of equal value with other mercurials.

Mercodel, a colloidal preparation of metallic mercury in which the particles of mercury are very minute and held in suspension, seems to have the most promising future of the newer forms of mercury. Tripp, in a personal communication to the author, stated that he had used mercodel in approximately 70 cases of syphilis, in all its stages, with uniformly good results, it seemed particularly effective in arsphenamin-resistant cases. He had noticed no ill effects whatever. Gauvain and Persky<sup>24</sup> have used mercodel in 27 cases, and report that the lesions disappear as rapidly with this drug as with any other now in use. Thrombosis did not occur. They believe this mercurial to be potent, safe, and worthy of further trial.

racts had been treated. Of these cases he reported 36 cases or 27½ per cent as being arrested cases, in 86 cases or 65 per cent the cataract was either cured or improved, making a grand total of 93 per cent of the cataracts which had responded favorably to his treatment. Such a "cure" if based on scientific truth is of the utmost importance, for the disease entity known as cataract is an ancient one, and has withstood the attack of ages of learned men who have sought to conquer it by every conceivable remedy other than the knife, with little or no success.

Such a revolutionary discovery as the finding of a mode of treatment which gives arrest in 85 per cent of the cases treated and improvement in over 50 per cent of the cases treated is worthy of further study by others of an unbiased mind. If these facts be true and we have a real definite mode of treating cataract of whatever form, it is vital that this fact should be broadcast not only to the medical profession but to the laity generally so that all may share in the benefits to be derived, for cataract is a common medical condition and if it is possible in early cases to stop the progress of cataract, the people generally should be as acquainted with the fact as they are now with the necessity of early treatment of cancer and tuberculosis and diabetes. If in addition to being able to prevent the formation of cataract in the early cases we can promise half of our cases cures after the cataract has formed and that the opacities will clear up, we truly have a remedy of inestimable value.

The ophthalmologist asks, are these facts true? He turns to the American Medical Association and enquires of the Council on Pharmacy and Chemistry whether the lens antigen treatment of cataract has been passed upon by their board and he finds that while this preparation has been presented to them they have not passed upon it for the ophthalmologists consulted all agree that the evidence of its usefulness was not acceptable. They await more evidence. It should be for ophthalmologists themselves to inform the council as to its efficacy and advocate its approval or disapproval by that impartial board.

At Bellevue Hospital and in connection with the Eye Department of New York University and Bellevue Medical School there has been going on for several years a study of this most timely subject, the medical treatment of cataract. It was considered momentous to first of all look about and see whether any of the remedies that so far had been advanced offered a real cure and if not, to dismiss them from discussion. Not an easy task but an essential one.

As in the case of many other diseases, the treatment of which is poorly understood, the

treatment of cataract has embraced nearly every conceivable remedy. Generally speaking, all have yielded most unsatisfactory results with the exception of the brilliant results in a very high percentage of cases following the various surgical procedures of extraction of the crystalline lens. The very fact that so many various modes of treatment have been advanced for the relief of this condition predisposes to the view that no worth while results were obtained with any. The treatment of incipient cataract then has resolved itself into the use of various medications in the conjunctival sac or injections beneath the conjunctiva in connection with internal medication which might aid in the process of staying the opacification or possibly actually aiding in its absorption. As many cataracts seem to be self-limiting and never go on to maturity and as some even seem to disappear automatically (although these cases are rare and their certainty is doubted by many authorities) the actual results obtained by the medication given is at best uncertain.

It is with this fact in mind that we approached the problem of arriving if possible at some definite treatment for the cure of cataract without resorting to surgery, or if this were impossible, frankly to admit that the condition was surgical and relegate drug therapy to its rightful position.

In studying the literature of what had previously been accomplished in this field of research we were struck by the account of the results found by Guyer and Smith. They began their work on the action of cytolytins and it was really only by chance that their work has had such bearing on the study of cataract. A brief outline of the work of these two men and their findings directly bearing on the work at hand might not be amiss. They found that lens tissue of rabbits and mice when injected into fowls excites the production of anti-bodies. The serum of the fowl when reinjected into rabbits and mice may attack in utero the lenses of the young of the species used as antigen. The reaction is not invariable, a majority or even all of the litter may not be acted upon, or a given individual may be affected only in one eye. The reason may be that the placenta is impervious to such anti-bodies except when there is an occasional rupture of a placenta blood vessel which might permit of direct mingling of foetal and maternal blood.

Various defects were noted among the offspring of animals injected with the serum. The liquefactions would indicate a true cytolytic effect, or the several lens proteins the fibrous one is the one upon which the sensitized serum seems to have operated. Whether

thiosulphate in lupus erythematosus, are the most recent outstanding discoveries in chemotherapy, and in all probability will eventually find a permanent and important place as therapeutic agents. This seems to me particularly true of the gold therapy in lupus erythematosus.

## NON-OPERATIVE TREATMENT OF CATARACT WITH REPORT ON LENS ANTIGEN TREATMENT\*

By ZENAS H ELLIS, M D, NEW YORK, N Y

**W**ITHIN the last few years the members of the medical profession have had many new discoveries displayed before them for their approval, a few of value, others of no worth. Perhaps the one that ophthalmologists

should be especially interested in is the announcement by Dr A E Davis at the International Congress of Ophthalmology in 1922 and at the American Ophthalmological Society in 1924 that he had arrived at a cataract preventative or cure without resort to surgery. In his report he announces that 72 patients with 131 cata-

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls N Y, May 11, 1927

is given with little pain and through that magic instrument, the hypodermic syringe

Before starting the treatment of these cases I conferred with Dr. Davis, and followed directions given by him. The patients were instructed to be abstemious regarding the use of alcohol and tobacco. They were told to drink three extra glasses of water daily, and to eat meat only once a day and then in moderation. They were given 10 cc of potassium iodide three times a day by mouth. On the first day one minim of lens antigen was injected intracutaneously, and on the following day the site of the injection was examined to determine the amount of severity of the reaction. They were then injected subcutaneously with  $\frac{1}{2}$  cc of lens antigen. The following day they were given 1 cc. The injection was increased 1 cc per day until 10 cc were reached. Some of the cases were run up as high as 15 or 18 cc per injection. The injections were given daily except on Sundays.

As some of the cases treated by lens antigen showed a stationary condition or very slow progress of the cataract, which might or might not be claimed to be due to the treatment which the cases received, it seemed wise to study a group of cases which have had no treatment whatever, either internal medication, drops or injections which also show a stationary action on the part of the cataract. In some of these cases there appeared to be a slight improvement in vision. This I believe is not due to the absorption of lens opacities but more apt to be due to either a better refraction at a later date, or else due to the fact that as the patient became more accustomed to the doctor there was better co-operation between the patient and the examiner. I am sure anyone doing a great deal of refraction on cases with lens opacities appreciates the fact that the mental attitude of the patient has a great deal to do with the vision which the patient has. It will also be noted that in some cases the opacities in one eye developed more rapidly than those in the other, although in all of the cases selected the growth of the cataract was slow. I present these cases to confirm a well established ophthalmological fact that some cataracts do become stationary and do not go on to maturity over a long period. This fact has been so well established I am sure in the minds of ophthalmologists that I hesitate to present these cases.

I present fourteen control cases all of which show in one or both eyes lens opacities which were stationary under observation for several years.

The patients that were treated were told that we were experimenting with a substance which we have every reason to believe would cure them of their cataracts and that it would not be necessary to operate. They were told, however, that in case the treatment failed to give them the desired relief, they would still have operative procedure to fall back upon. I believe we succeeded in convincing most of the cases that we really believed that the treatment would cure them. We did this in order to obtain the best possible co-operation on the part of the patient and also to have the advantage of any psychological effect. Most of the patients co-operated extremely well. Only one case in the series developed anaphylactic shock from the injections. I believe that this was a true anaphylactic shock, as it came on at the end of the thirtieth treatment. The patient was unconscious for five or six minutes but later responded to an injection of adrenalin. About one-fourth of the cases developed a mild dermatitis at the seat of the injection and complained a great deal about the itching accompanying the dermatitis. The area at the seat of the injection in these cases was raised and had an elevated temperature. These skin reactions were of various sizes and shapes and varied greatly in severity. No inflammatory reaction of the eyes was noted in any of the patients treated.

#### SUMMARY

Types of cataracts treated	Traumatic	2
	Cortical	15
	Sclerosed Nucleus	5
	Diabetic	4
	Complicating Glaucoma	1
	Total	27

Cases which showed progress of the cataract—14

Cases which showed no change in the progress of the cataract—13

Cases which showed absorption of the cataract by slit lamp examination or improvement in vision—None

Practically all of the cases noted a general tonic effect from the lens protein

#### DISCUSSION OF DR. ELLIS'S PAPER

By A. EDWARD DAVIS, M.D., NEW YORK, N. Y.

Dr. Ellis was kind enough to give me the main points in his part of the paper on the non-operative treatment of cataract.

(1) In no case had lens opacities been absorbed.

(2) In about one-half of the cases the

the other ingredients were also affected was not determined

The clouding which occurred in other lenses might either be the result of a cytolsin or precipitin. The important point is that opacities which may be permanent can be produced by specific sera. In the most striking case the affected lens was so diminished in size that the whole eye was microphthalmic.

It will be noted that Guyer and Smith found that the anti-bodies injected into animals had no effect on the lens or any other of the orbital contents of the mother, but only of the offspring, also the lenses of males were unaffected. I believe this is a point of great significance in the study of the effect of lens antigen.

It will also be noted that Guyer and Smith believe that the absorbing effect was possible because of the presence of blood vessels in the embryonic lens, whereas in the senile cataract case poor nutrition of the lens associated with poor lymphatic circulation is partly responsible for cataractous changes. If this is true how can we hope for liquefaction of a senile cataract by the same process as resulted in the liquefaction of the embryonic lens? It will also be noted that they report in several cases that the lens became cloudy and opaque (the result of cytolsin and precipitation). This is of course the reverse of what we are striving for, but it may be a very important point.

Two years later Guyer and Smith had carried their work along so that they report in the *Journal of Experimental Zoology* that the defects found in the eyes of their rabbits were carried to the sixth generation by breeding, and they feel that the evidence established a cleancut case of inheritance of specific modification produced by extrinsic factors.

They are not sure that the result should be reckoned as an example of the inheritance of a somatic modification, that is a change produced in the lens of the intrinsic young which in turn has induced a change in the lens producing constituents in the germ cells of these young, or a simultaneous change in the eye and in the germ cells of the young.

A noteworthy fact was that once the defects were established without subsequent treatment they became more and more pronounced in successive generations. Lens antigen would seem then to have a cumulative action. The presence of isolsins can be proved by the precipitation test. These once established in the embryonic circulation should be as effective in modifying germinal factors as corresponding anti-bodies introduced into the embryo through the placenta of the mother.

I have gone over this work in some detail as it is the basis of Dr. A. E. Davis' treatment of cataract with serum. That is he believes

that a solution of emulsified lens of an animal injected into the human will cause the active formation of anti-bodies which will seek out the lens and invade it and cause the absorption of its opacities. He lays no claim I believe that it will actually absorb normal lens substance. Why these anti-bodies engendered by injected normal lens substance should act on abnormal lens protein has never to my knowledge been explained. If the work of Guyer and Smith is correct, then we should rather expect no effect on the lens of the patient but rather if it were a female that her children would be born into this world with varying types of eye defects, and lenses in different stages of opacification and absorption. Let us hope that Guyer and Smith are wrong or that the patients of my lens protein clinic are all beyond the child-bearing period.

The patients were selected from the clinics of Dr. John M. Wheeler at Bellevue Medical School and Bellevue Hospital, and the New York Eye and Ear Infirmary. We endeavored to select cases of all types of cataract and not limit ourselves to one particular form, and attempted to determine whether or not any particular group of cases yielded to treatment better than others. It is my understanding that Dr. Davis now advises the use of lens antigen only in incipient senile cataract where the vision is 20/70 or better.

Now it appears to anyone that has had any experience with cataract formation (and all authorities are agreed on this point, at least) that cataracts may appear and then grow slowly or rapidly or may become stationary, all depending upon conditions of which we have but little knowledge but probably due to varying metabolic changes. Now it is very easy to delude one's self in endeavoring to effect a cure of any disease, and medical history is filled with these delusions, even the great Koch and Pasteur were not immune from the flights of their own imaginations and assumed that they had conquered disease, and found the cure, only to have their fond dreams end in ignominious defeat. Sincere they were, but their failure to keep their feet on the solid rock of scientific fact brought them heartaches, and in the case of Koch, nearly ruined the good work previously done and on which his fame today rests. So it is in the search for a cure for cataract. The eye is so sensitive to any change of vision, that one should be ever alert as to apparent effects of treatment, and not be misled by the patient's optimism or desire for relief.

Certain it is that given a person with cataract of any origin, and a realization that vision is diminishing and the knowledge that it may go on to blindness, we will find that person most susceptible to treatment if the treatment

Now, from my experience with senile cataract, I would say that Dr Wells's estimate of the number of cases of untreated incipient senile cataract that come to operation is entirely too optimistic. Just to think of only one per cent maturing and but five per cent losing useful vision! If 90 per cent of this 6 per cent that came to operation are successful, then one per cent of cataract cases come to blindness, a consummation devoutly to be wished for, but alas! not realized in the practice of the average ophthalmologist.

I must say my own experiences more nearly coincide with Dr E C Ellett of Memphis, Tenn, who in discussing Dr Jackson's paper (Senile cataract under hygienic care) states "All of us can duplicate these experiences with cases that have gone on for many years. I can think of several that I have observed for over twenty years without material change, but I do not think we ought to go away with the impression that the majority will not in the future, as they have in the past, mature and have to be extracted."

I, too, have observed patients for more than twenty years, one for twenty-seven years, who still maintained a modicum of vision, and this patient of 27 years' duration, though "satisfied" himself with his vision had to be assisted about during his last years.

Dr Edward Jackson makes a very significant remark in closing the discussion of his paper, above cited "Now as to occupation. In a general way the former occupation of the patient has been give up. Most of these patients have fallen into the habits of old age, to a considerable extent, and their cases must be considered from that point of view." But most of us in

active practice have many patients with incipient cataract that do not all fall in that class or point of view. They are active business or professional men, and must earn a living and are most anxious to maintain useful vision, and are not satisfied to get along some way, and it is this type of case that should have the lens antigen treatment.

For example, I have one excellent surgeon in New York City, whose vision was brought up to normal by the lens antigen treatment, and he is actively engaged in practice. His father before him, who had nothing but hygienic care of eyes, went to double operation for cataract, and this surgeon's sister also had only hygienic care of the eyes, went to operation, and, although successfully operated on, later lost her vision through detachment. So this family history would indicate that lens antigen was of value in this instance in stopping cataract. And this brings me to speak of high myopes with beginning cataract. The oculist who does not give such patients the benefit of non-operative treatment, does not, in my opinion, do justice to his patient. We should not only give such patients the best hygienic care, but they should also have the benefit of specific protein injections. In fact, every incipient senile cataract, except the nuclear type, should have a specific lens antigen treatment.

With further original research work on the nutrition of the crystalline lens as conducted by Wheeler and Kinby, and further improvement of lens antigen as produced by Woods, even better results, I predict, will be obtained in the treatment of cataracts, by means of lens antigen injections.

## DIAGNOSIS AND TREATMENT OF GOITER\*

By WALTER T DIVER, M D, F.A.C.S., TROY, N Y

**T**O thoroughly discuss any particular phase of thyroid diseases would be obviously impossible in such a short paper. Therefore it has occurred to me that a general discussion about conditions of interest to us all would meet with more favor than a lengthy and exhaustive article dealing with the more theoretical aspects of this subject.

I do not propose either to speak to you this afternoon of the operative surgery of the thyroid gland. We all know that a competent surgeon, experienced and skillful, can be depended upon to handle the work.

But I do desire to discuss some of the clinical aspects of the more common diseases of the thyroid, namely, Simple or Endermic Goiter, and Exophthalmic, or Graves' Disease,

and deal lightly, also, with their etiology, pathology, diagnosis and treatment.

If we omit for the present, Malignant Disease, Acute Inflammation and certain of the rare forms of Thyroid enlargement, there remain two varieties of Goiter.

The first is Simple or Endermic Goiter, and to begin with I wish to emphasize that Simple Endermic Goiter is not a hypertrophy of the gland. It is essentially a degeneration.

The enlargement of the gland in the earliest stages in which I have been able to observe, consists primarily in a distention of the organ with colloid, with some atrophy of the epithelial elements. In this respect it differs entirely from the Goiter of Graves' Disease (Exophthalmic Goiter) which is due to an increase in the cellular elements of the gland. The mis-

progress of the cataract had been arrested

(3) The patients were out-patients at Bellevue

(4) Fourteen patients with non-progressive cataracts (seen in Dr Wheeler's private office) were used as control

As regards the first point, the non-absorption of lens opacities, I may say while the spiculae do not often disappear, though I have seen a few such cases (and Connor of Detroit has reported such cases) the general cloudiness of the lens often clears and in this way the vision is often improved. Opaque lens fibres are also absorbed by lens antigen. I think with further observations Dr Ellis will find such cases

Second point—the arrest of the progress of the cataract in about fifty per cent of the cases treated is an excellent showing for the antigen, considering that the patients were out-door where little control can be had over them

This per cent of arrest is much greater than that reported by Jackson (*Senile cataract under hygienic care*) where he gives 17.39 per cent as remaining stationary. The difference is certainly worth striving for

In my own experience, by the use of lens antigen, the percentage of arrested and improved cataracts (private patients) is much higher

Dr Knighton, my associate, has just looked over a record of 176 eyes, in which 37.5 per cent were improved and 32.3 per cent were arrested, the two combined equalling about 70 per cent

Third point—out-patient clinic patients are not nearly so favorable for treatment as private patients and for two or three reasons, (a) they usually come later in the progress of disease, (b) they are in poor physical condition, (c) they often cannot or do not have regular and full treatments

Fourth point—taking non-progressive private patients without treatment as a standard with which to compare progressive cataracts in clinical patients who received lens antigen treatment, is not a fair comparison of results in any sense of the word. Cases of a like nature, either progressive or non-progressive, under as nearly similar surroundings as possible, one group to receive hygienic care the other to have the lens antigen injections, should be selected for comparison, if we wish to arrive at a decision between the superiority of the methods

Dr Edward Jackson has reported 108 private cataract patients (207 eyes) under observation for more than two years, and a most valuable contribution it is, giving us a standard to measure the success or failure of other methods of treatment

Taking his results as a standard I am giving

the results in 176 eyes in my own private practice, and make a comparison of results

Dr Jackson's cases have been under observation for longer periods than my own

<i>Dr Jackson's</i>	<i>Improved</i>	<i>Stationary</i>	<i>Worse</i>
Uncomplicated (184 eyes)	15 8.15%	36 19.57%	133 72.28%
All cases (207 eyes)	16	36	155
2-21 yrs	7.73%	17.39%	74.88%
<i>Dr Davis'</i>	<i>Improved</i>	<i>Stationary</i>	<i>Worse</i>
Uncomplicated (113 eyes)	36	33	44
1-4½ years	31.8%	29.2%	39.0%
Three months and more (162)	59 36.4%	52 32.1%	51 31.5%
All cases (176 eyes)	66 37.5%	57 32.3%	53 30.2%

In looking over Jackson's table I note the vision when first observed and when last observed and find that 155 eyes had reduced vision. This, although, Dr Jackson, in the body of his paper says only 100 eyes had diminished vision which would be 48.3 per cent instead of 155 eyes which would be 74.88 per cent

In either instance it will be noticed that in all cases, uncomplicated and complicated—that the advantage is decidedly in favor of the cases treated by the antigen

In the untreated cases improvement occurred in 7.73 per cent, in the treated cases 37.5 per cent, or about five to one

Vision worse, in untreated 74.88 per cent, or if only 100 eyes were worse (as stated in body of paper 48.3 per cent) while in the treated cases it was only 30.2 per cent. These parallel columns speak for themselves. So according to the statement of Dr Wells of Boston—"Unless one can show that his results with a certain drug, internal or external, or the indicated remedy or mechanical appliance are better than the untreated case, he has not proved the therapeutic value of his interference"

These data would indicate that my method of treatment was of decided value

Dr Wells in 1915 in reporting his cataracts which he indexed from 1900 to 1915 has this to say "Many have been watched at varying intervals from 10 to 15 years. Of course, many have been lost sight of, but as near as can be estimated not more than 1 per cent of the truly incipient cases have matured, and not more than five per cent have materially advanced. From this it appears that the prognosis of incipient senile cataract untreated is extremely good"

Now, from my experience with senile cataract, I would say that Dr Wells's estimate of the number of cases of untreated incipient senile cataract that come to operation is entirely too optimistic. Just to think of only one per cent maturing and but five per cent losing useful vision! If 90 per cent of this 6 per cent that came to operation are successful, then one per cent of cataract cases come to blindness, a consummation devoutly to be wished for, but alas! not realized in the practice of the average ophthalmologist.

I must say my own experiences more nearly coincide with Dr E C Ellett of Memphis, Tenn, who in discussing Dr Jackson's paper (Senile cataract under hygienic care) states "All of us can duplicate these experiences with cases that have gone on for many years. I can think of several that I have observed for over twenty years without material change, but I do not think we ought to go away with the impression that the majority will not in the future, as they have in the past, mature and have to be extracted."

I, too, have observed patients for more than twenty years, one for twenty-seven years, who still maintained a modicum of vision, and this patient of 27 years' duration, though "satisfied" himself with his vision had to be assisted about during his last years.

Dr Edward Jackson makes a very significant remark in closing the discussion of his paper, above cited "Now as to occupation. In a general way the former occupation of the patient has been give up. Most of these patients have fallen into the habits of old age, to a considerable extent, and their cases must be considered from that point of view." But most of us in

active practice have many patients with incipient cataract that do not all fall in that class or point of view. They are active business or professional men, and must earn a living and are most anxious to maintain useful vision, and are not satisfied to get along some way, and it is this type of case that should have the lens antigen treatment.

For example, I have one excellent surgeon in New York City, whose vision was brought up to normal by the lens antigen treatment, and he is actively engaged in practice. His father before him, who had nothing but hygienic care of eyes, went to double operation for cataract, and this surgeon's sister also had only hygienic care of the eyes, went to operation, and, although successfully operated on, later lost her vision through detachment. So this family history would indicate that lens antigen was of value in this instance in stopping cataract. And this brings me to speak of high myopes with beginning cataract. The oculist who does not give such patients the benefit of non-operative treatment, does not, in my opinion, do justice to his patient. We should not only give such patients the best hygienic care, but they should also have the benefit of specific protein injections. In fact, every incipient senile cataract, except the nuclear type, should have a specific lens antigen treatment.

With further original research work on the nutrition of the crystalline lens as conducted by Wheeler and Kinby, and further improvement of lens antigen as produced by Woods, even better results, I predict, will be obtained in the treatment of cataracts, by means of lens antigen injections.

## DIAGNOSIS AND TREATMENT OF GOITER\*

By WALTER T DIVER, M.D., F.A.C.S., TROY, N. Y.

**T**O thoroughly discuss any particular phase of thyroid diseases would be obviously impossible in such a short paper. Therefore it has occurred to me that a general discussion about conditions of interest to us all would meet with more favor than a lengthy and exhaustive article dealing with the more theoretical aspects of this subject.

I do not propose either to speak to you this afternoon of the operative surgery of the thyroid gland. We all know that a competent surgeon, experienced and skillful, can be depended upon to handle the work.

But I do desire to discuss some of the clinical aspects of the more common diseases of the thyroid, namely, Simple or Endermic Goiter, and Exophthalmic, or Graves' Disease,

and deal lightly, also, with their etiology, pathology, diagnosis and treatment.

If we omit for the present, Malignant Disease, Acute Inflammation and certain of the rare forms of Thyroid enlargement, there remain two varieties of Goiter.

The first is Simple or Endermic Goiter, and to begin with I wish to emphasize that Simple Endermic Goiter is not a hypertrophy of the gland. It is essentially a degeneration.

The enlargement of the gland in the earliest stages in which I have been able to observe, consists primarily in a distention of the organ with colloid, with some atrophy of the epithelial elements. In this respect it differs entirely from the Goiter of Graves' Disease (Exophthalmic Goiter) which is due to an increase in the cellular elements of the gland. The mis-

\* Read before the Third District Branch Meeting, at Troy, N. Y., October 1, 1927.

progress of the cataract had been arrested

(3) The patients were out-patients at Bellevue

(4) Fourteen patients with non-progressive cataracts (seen in Dr Wheeler's private office) were used as control

As regards the first point, the non-absorption of lens opacities, I may say while the spiculae do not often disappear, though I have seen a few such cases (and Connor of Detroit has reported such cases) the general cloudiness of the lens often clears and in this way the vision is often improved. Opaque lens fibres are also absorbed by lens antigen. I think with further observations Dr Ellis will find such cases

Second point—the arrest of the progress of the cataract in about fifty per cent of the cases treated is an excellent showing for the antigen, considering that the patients were out-door where little control can be had over them.

This per cent of arrest is much greater than that reported by Jackson (*Senile cataract under hygienic care*) where he gives 17.39 per cent as remaining stationary. The difference is certainly worth striving for.

In my own experience, by the use of lens antigen, the percentage of arrested and improved cataracts (private patients) is much higher.

Dr Knighton, my associate, has just looked over a record of 176 eyes, in which 37.5 per cent were improved and 32.3 per cent were arrested, the two combined equalling about 70 per cent.

Third point—out-patient clinic patients are not nearly so favorable for treatment as private patients and for two or three reasons, (a) they usually come later in the progress of disease, (b) they are in poor physical condition, (c) they often cannot or do not have regular and full treatments.

Fourth point—taking non-progressive private patients without treatment as a standard with which to compare progressive cataracts in clinical patients who received lens antigen treatment, is not a fair comparison of results in any sense of the word. Cases of a like nature, either progressive or non-progressive, under as nearly similar surroundings as possible, one group to receive hygienic care the other to have the lens antigen injections, should be selected for comparison, if we wish to arrive at a decision between the superiority of the methods.

Dr Edward Jackson has reported 108 private cataract patients (207 eyes) under observation for more than two years, and a most valuable contribution it is, giving us a standard to measure the success or failure of other methods of treatment.

Taking his results as a standard I am giving

the results in 176 eyes in my own private practice, and make a comparison of results.

Dr Jackson's cases have been under observation for longer periods than my own.

<i>Dr Jackson's</i>	<i>Improved</i>	<i>Stationary</i>	<i>Worse</i>
Uncomplicated (184 eyes)	15 8.15%	36 19.57%	133 72.28%
All cases (207 eyes)	16 7.73%	36 17.39%	155 74.88%
2-21 yrs			
<i>Dr Davis'</i>	<i>Improved</i>	<i>Stationary</i>	<i>Worse</i>
Uncomplicated (113 eyes)	36 31.8%	33 29.2%	44 39.0%
1-4½ years			
Three months and more (162)	59 36.4%	52 32.1%	51 31.5%
All cases (176 eyes)	66 37.5%	57 32.3%	53 30.2%

In looking over Jackson's table I note the vision when first observed and when last observed and find that 155 eyes had reduced vision. This, although, Dr Jackson, in the body of his paper says only 100 eyes had diminished vision which would be 48.3 per cent instead of 155 eyes which would be 74.88 per cent.

In either instance it will be noticed that in all cases, uncomplicated and complicated—that the advantage is decidedly in favor of the cases treated by the antigen.

In the untreated cases improvement occurred in 7.73 per cent, in the treated cases 37.5 per cent, or about five to one.

Vision worse, in untreated 74.88 per cent, or if only 100 eyes were worse (as stated in body of paper 48.3 per cent) while in the treated cases it was only 30.2 per cent. These parallel columns speak for themselves. So according to the statement of Dr Wells of Boston—"Unless one can show that his results with a certain drug, internal or external, or the indicated remedy or mechanical appliance are better than the untreated case, he has not proved the therapeutic value of his interference."

These data would indicate that my method of treatment was of decided value.

Dr Wells in 1915 in reporting his cataracts which he indexed from 1900 to 1915 has this to say "Many have been watched at varying intervals from 10 to 15 years. Of course, many have been lost sight of, but as near as can be estimated not more than 1 per cent of the truly incipient cases have matured, and not more than five per cent have materially advanced. From this it appears that the prognosis of incipient senile cataract untreated is extremely good."

has attained the more one is impressed with the fact that in many cases it is a difficult procedure. Especially difficult do we find this in determining the difference between Exophthalmic Goiter before exophthalmus and advanced adenoma of the Thyroid. Then, again, when we have a combination of Exophthalmic Goiter (Goiter, Basedow) and long standing adenoma in the same patient, another when we sometimes have to deal with a combination of hyperthyroidism, due to iodine or iodine-hyperthyroidism in a degenerated or toxic adenoma and exophthalmic goiter.

Diffuse colloid goiters are often mistaken for beginning Exophthalmia, and vice versa.

You may answer and say, "Why, the metabolism test, the nervous symptoms, the heart, many ways of examination that will clear the picture." But identical symptoms may occur in any or all of these cases and it is a most difficult job and taxes one's entire resources at times.

I will not go into detail on this question because time is too short. I will, however, touch upon one of the most important conditions which we have to deal with in differential diagnosis.

Authorities all agree on the difficulties encountered sometimes in making a differential diagnosis between Pulmonary Tuberculosis in the incipient stage, and early or non-suspected thyroid enlargement. Goiter and tuberculosis in their early stages effect the system in nearly the same way, so similar are their manifestations.

We have, as Sloane writes, the incipient case of tuberculosis without demonstrable lung lesion, resembling mild Exophthalmic Goiter.

2nd The "formes frustes," or mild type of Exophthalmic Goiter, resembling early tuberculosis.

3rd Co-existent tuberculosis and goiter.

Tubercular patients should always be carefully watched for evidence of goiter, both for hypo and hyperthyroidism.

In many cases, it is true, where active symptoms of the disease are present, can the two diseases be readily differentiated, such as well marked physical signs in the chest in T. B. It is also true that in cases of well-marked hyperthyroidism a diagnosis can be made across the room—but this is not true in early cases.

In early tuberculosis there is lassitude, fatigue, loss of appetite, fever, loss of weight, also some nervousness, rapid pulse, night sweats and higher metabolic rate. These can be the symptoms, also, of early goiter, in addition, however, we have tremor, palpitation, increased metabolism, somewhat higher in enlarged thyroid. That a careful study in each case will make it much more possible for us to

arrive at an accurate differential diagnosis between incipient hyperthyroidism and incipient tuberculosis and avoid the necessity of sanitarium treatment for incipient goiter cases and, likewise, be able to save a number of cases of early tuberculosis from being treated surgically.

I have had in my experience, for many years, a number of cases of this kind. When there is a question I turn the case over immediately to an expert on the chest. When there is a doubt, rest being the treatment for both conditions over a long period of time, improvement will unquestionably follow, then, as time goes on when more distinct signs present themselves, more direct measures can be instituted.

Many times the co-existence of the two conditions is present, although this opinion is not shared by all authorities.

From personal experience I am absolutely positive that both conditions often present themselves in the same case.

Sloane reports that he has operated 400 cases in the last fifteen years. These patients were known to have tuberculosis before operation and practically all have gained in weight and satisfactory improvement.

I have had seventeen cases in my experience within the last three years. Several were rejected at the various sanitariums on account of their goiters. The majority of these cases were from northern New York, about Saranac, Tupper Lake and Lake Placid, and several from this vicinity. It was surprising what a distinct change for the better took place in all of them. They were all done under local anaesthesia, which gives no appreciable shock.

Hypo-thyroidism=lack of proper amount of thyroid secretion.

#### TREATMENT

The treatment of hypothyroidism is quite satisfactory, as far as the control of the condition is concerned, but not very satisfactory as to cure, the physician must, however, have fair knowledge of what he can hope to accomplish. Underlying it all he must have a sure grasp of all physiological and pathological factors involved and also the physiological action of the drug or drugs which he proposes to use. He must also have an understanding of the certain essentials in administering the drug to obtain the best results. The failure of treatment in the past has been because of a lack of knowledge of these essentials.

The internal secretion of the Thyroid Gland, thyroxin, controls the energy-producing mechanism of the body. Decreased energy is lowered basal metabolism. This is the most outstanding, single symptom in any type of hypothyroidism. This is true in cretinism and frank myxedema or post-operative myxedema.

use of the term "hypertrophy" as applied to Simple Goiter is very widely spread in literature, at the present day. It is especially found in the writings of laboratory researchers and those of physicians who have fewer opportunities of seeing the inside of a Goiter than have surgeons who operate upon them.

If the cause that produces the increase of colloid, almost certainly an irritant of some kind, be removed, the gland quickly returns to normal. Most Goiters of adolescence undergo a spontaneous cure, as soon as the physiological demand for increased thyroid secretion for trophic purposes has ceased. This is seen frequently in practice. This type of Goiter is evidently a deficiency disease, due to a relative lack of iodine. If the cause persists, a fibrosis, due to slight chronic inflammation sets in and the condition gradually becomes a permanent one.

In Goiters of considerable size, or long duration, this interstitial fibrosis may be most marked and is frequently accompanied by calcification.

The retention of colloid leads to the presence of cysts, which may coalesce into large ones, but nearly all the larger cysts of Goiter are formed by the breaking down of ill-formed masses of Thyroid tissue, surrounded by a more or less well-marked capsule. These masses are called "Adenomata." It is a question whether the word "Adenoma" is a correct one. A more frequent name given to the condition by continental surgeons is "Struma Nodosa" or "Nodular Goiter." But adenoma is the term generally applied in America.

Marine says "The suggestion by Woeffler that these nodules arise from fetal thyroid rests, and the introduction by Bellroth of the term 'Fetal Adenoma,' has served unduly to emphasize the hypothesis of their fetal origin. While a few may arise in this way there is a general acceptance of the view that the great majority must arise from differentiated Thyroid tissue, usually beginning in the Goiter of Adolescence."

It is in this variety of Goiter which comes on in early life, even in the earliest period of fetal life, that a complete atrophy of secreting elements is found. The type that leads to cretinism, deafmutism, idiocy and dwarfism, which is so prevalent in Switzerland.

It is claimed by some authorities that with the rate Simple or Juvenile Goiter is increasing in our country a similar condition is likely to prevail here if careful measures are not taken.

Marine, continuing, says that Simple Goiter in contra-distinction to Exophthalmic Goiter is as prevalent in lower animals and can be readily induced in them.

Galli Valerio of Lusanne, says that the

etiology of Endemic Goiter is not fully understood. Of the numerous theories that which regards drinking water as the cause of goiter is at once the oldest and best supported by facts and experiment.

The poison of Goiter in drinking water is either a specific substance, or a specific germ or groups of germs, especially intestinal flora, which produce toxic substances that act upon the Thyroid Gland. Apart from water supply, in-breeding is a predisposing factor in cretinism and deafmutism.

The theory that Goiter is caused by a deficiency of iodine cannot be accepted.

(a) Because even where iodine is in excess (on sea coast), goiter exists.

(b) Because deficiency of iodine causes atrophy, not hypertrophy of the Thyroid.

Iodine is merely some sort of an antidote to Goiter, as is quinine to malaria. Deficiency of quinine does not give rise to malaria, neither does deficiency of iodine give rise to Goiter.

Bircher says that the etiological factor of Goiter, and the conditions which favor its prevalence, are of a varied nature. One cannot admit a uniform etiological factor.

We will now devote a little time to another type of goiter very different from that which we have first considered, a variety which we see a great deal of in this vicinity and other localities about the United States and which is not so prevalent in Europe. This is Exophthalmic Goiter or Graves' Disease. It is characterized by an excess of cellular elements and a diminution or absence of colloid. In its various forms it seems to be a hypertrophy or hyperplasia of the gland.

We must admit that we are no closer to the etiology of this disease than we were at the beginning of our work. It is, no doubt, caused by an irritant of some kind. Whether it be an infection, some predisposing constitutional factor, a psychic stimulus from nerve strain, or shock, or accident, cannot be said. It is increasing, however, in this country and influenza seems to be a predisposing cause.

Both Exophthalmic Goiter and Colloid Goiter, it would appear, are closely related to each other, the two types occurring in high ratio in the same districts.

Now these are the two chief varieties which we have to contend with about here, and the different phases and degrees of enlargement of either, or both, separate or combined, take in the principal material which we physicians and surgeons see.

#### DIAGNOSIS

Offhand, men who are not familiar with Goiter would say that it is an easy task to make a diagnosis of the various forms of pathological Thyroid. But the more experience one

goiter, then one has to be extremely careful and administer iodine before removal

The hyperthyroidism of advanced adenoma is characterized by an insidiousness, by an erratic course over a long period of years of low intensity, finally after a period of years, the average being about seventeen or eighteen, a distinct clinical hyperthyroidism develops. In the hyperthyroidism of adenoma, a surgical procedure, is directed to the removal of the tumor. Ligation is of no value, iodine is of no value

Wegelin and Marine both conclude that these adenomata are potential malignant tumors as is indicated by the fact that they may continue to grow after the rest of the thyroid has ceased to grow and that a larger percentage of malignant epithelial tumors of the thyroid arise from them

#### TREATMENT OF EXOPHTHALMIC GOITER

Plumber's remarkable discovery of the efficiency of the administration of iodine as a pre-operative measure has largely done away with the long, drawn out preparatory hospital treatment, with the resulting drain on the patient's finances and the ligation and many stage operation are practically matters of the past, in addition to this patients with severe toxic hyperthyroidism and auricular fibrillation are operated upon without unwarranted risk. Even those cases that have gone beyond the type we have just considered, even those approaching the terminal stage, cases showing actual signs of true heart failure can be justifiably operated, in selected stages

I have had some rather desperate cases of this character that I have operated upon against the advice of the family physician and they are all living and in comfort

The characteristic and outstanding feature of Graves Disease (Exophthalmic Goiter Hyperthyroidism) is the fact that its complete elaboration takes place within a relatively short space of time, and the case when first seen presents usually a complete clinical picture. All the features of the disease are outstanding and present. In the hyperthyroidism of Graves' Disease, surgical procedures are directed to diminish the actual amount of thyroid tissue by removal of varying amounts of hyperplastic tissue

In the hyperthyroidism, due to exophthalmic goiter, iodine should never be administered until the patient has decided to submit to an operation and be confined to a hospital. When the patient has had sufficient rest in bed iodine should be given approximately ten to twenty-one days before the day decided upon to operate. The iodine is used to counteract the terrific and sometimes fatal reaction which patients have 24 to 48 hours post-operatively, even after the most perfect thyroidectomy

#### TREATMENT OF IODINE HYPERTHYROIDISM

For several years, however, the promiscuous use of iodine in the form of table salt, etc., in the treatment of goiter by certain physicians and persons of no medical knowledge, has given rise to a condition to which the name Iodine Hyperthyroidism has been applied

Within the last year several cases have come to our clinic and it has only been with the greatest of care that these patients have been saved and one case died before we were able to readjust the treatment

Any type of goiter may undergo a change, even when in quiescent condition, if iodine is not intelligently given

Although I used the words "Simple or Endemic" at times, this is not an endemic locality for goiter and a wholesale use of this drug is decidedly a reprehensible practice. We, in this vicinity, must treat each case individually and as I have already said, "Know when to use, what and how to use, the drug indicated"

#### SUMMARY

In conclusion, I will sum up the points upon which I have tried to lay stress as follows

1 Simple goiter is not a hypertrophy but essentially a degeneration of the thyroid gland. The gland is not overactive, but underactive

2 Whatever may be the connection between iodine and the thyroid gland there is no reason for believing that a lack of iodine has anything to do with the causation of goiter

3 It is quite certain that, at least in the majority of cases, the disease is produced through the agency of drinking water

4 That there is a frequent co-existence of goiter and tuberculosis in the same patient. And diagnostic difficulties are many at times

5 The essentials should be thoroughly understood and carefully considered each time treatment for a hypothyroid patient is contemplated, and it should be briefly explained to the patient in order to obtain full cooperation

6 That treatment of simple goiter, if possible, should be started before birth, and treatment of adenomatous goiter before hyperthyroid symptoms have markedly progressed, and that iodine in this particular variety should never be given. That exophthalmic runs a rapid course and should be recognized as soon as possible and the proper surgical measures observed

7 That it is an extremely serious practice to treat adenoma of the thyroid with iodine, especially after 25 years of age, for fear of producing iodine hyperthyroidism, and that iodine should only be given to an exophthalmic goiter case when the patient has given consent to be operated upon and has entered the hospital

Other symptoms are direct results of this lowered metabolism

Lowered metabolism, being constant and measurable, gives us our most valuable data in directing treatment

Basal metabolism varies from time to time in individual patients and this fact should be considered in a treatment that is satisfactory

Basal metabolism of the patient under observation should be taken once every day for at least three or four days, because these repeated metabolism tests enter into the accuracy of the individual metabolic rate. The true rate will not, nor should not, vary three to five points

The specific treatment is the supplying daily amounts of thyroxin or desiccated thyroid gland to make up for the deficiency in the individual patient

Damage already done will probably not be made up, if treatment is started late. As for instance, nephritis or damage to other organs, but it can safely be said that the energy regulating mechanism can be made physiologically normal

One must know the physiological action of thyroxin the active principal of the thyroid gland, and the amount of these ingredients in the different preparations on the market. The relation between the exact metabolic reading and the computed daily dose based on that reading

The average normal human body contains approximately 14 Mg of thyroxin, the daily output 0.75 Mg. If a patient has no thyroid secretion he must be supplied with 0.75 mg of thyroxin or its equivalent in desiccative thyroid glands

Absorption by mouth is slow, compared to intravenous treatment. The basal metabolic rate can be raised in from 24 to 48 hours if a proper dose of thyroxin is given intravenously, by mouth it takes about twelve days and the results of the same dose exhausted in about one month

The thyroid preparations on the market vary. One should know the strength of preparation being used. Large doses are apt to cause a severe reaction and necessitate the patient going to bed and being watched carefully

If proper doses are given, results can be seen, if tests are taken at end of two weeks and then later in about eight or ten weeks, continuing for a year. The dose should be given every single day. In order to meet the growth requirements the amount has to be changed every year or so

TREATMENT—SIMPLE, COLLOID AND ADENOMATOUS GOITER

I have now under observation in out-clinics

over two hundred cases of Adolescent or Juvenile Goiter or Thyroid enlargement, between the ages of six and twenty. These are mostly school children from the near vicinity, say within a radius of one hundred miles. I have suggested to several physicians and specialists who do a great deal of maternity work to carefully watch their cases and prescribe iodine medication, when in their opinion there exists a possibility of goiter in the mother, in order that our medication may be administered and be effective as early as possible

In these two hundred cases under observation, between six and twenty, I have not seen any great improvement in retarding or lessening enlargement from internal medication. We must, however, keep it up as we know it to be a long, drawn out treatment

The main results will be obtained by medicating the pregnant mother. After there is a pathological beginning, it is difficult to create a reverse in conditions

From my experience and discussions, which I had with other men of our profession, I have come to the conclusion that more definite results can be procured with iodine than with the various preparations of the Thyroid Gland. Iodine deficiency is probably the cause of Simple Goiter and iodine should be given in an exact dose and under the direction of a physician who will carefully watch his patient and note results

I have followed the practice of most goiter men in giving a coated tablet containing 10 mg of iodine, either once or twice a week during the year

In non-toxic adenomatous goiter, which generally comes on about puberty and no doubt originates from an untreated colloid goiter, the same treatment can be continued, but with care, until about 20 to 21 years of age. The iodine will have no effect upon the nodules but it may lessen the size of the rest of the gland and help cosmetically. These goiters seldom originate after 25 years of age

After an adenoma has developed, no amount of iodine will remove the growth. After 25 years, or earlier, it is well to suggest the removal of the gland for safety's sake

In a large percentage of these adenomas hyperthyroidism will develop and cause great damage to the heart and all the other vital organs. Many will enlarge and become unsightly, some grow down under the sternum, extending even into the thorax and the back pressure on the heart in conjunction with laryngeal nerve pressure makes a very serious state of affairs

Many times advanced toxic or degenerated adenoma has associated with it exophthalmic

goiter, then one has to be extremely careful and administer iodine before removal

The hyperthyroidism of advanced adenoma is characterized by an insidiousness, by an erratic course over a long period of years of low intensity, finally after a period of years, the average being about seventeen or eighteen, a distinct clinical hyperthyroidism develops. In the hyperthyroidism of adenoma, a surgical procedure, is directed to the removal of the tumor. Ligation is of no value, iodine is of no value.

Wegelin and Marine both conclude that these adenomata are potential malignant tumors, as is indicated by the fact that they may continue to grow after the rest of the thyroid has ceased to grow and that a larger percentage of malignant epithelial tumors of the thyroid arise from them.

#### TREATMENT OF EXOPHTHALMIC GOITER

Plumber's remarkable discovery of the efficiency of the administration of iodine as a pre-operative measure has largely done away with the long, drawn out preparatory hospital treatment, with the resulting drain on the patient's finances and the ligation and many stage operation are practically matters of the past, in addition to this patients with severe toxic hyperthyroidism and auricular fibrillation are operated upon without unwarranted risk. Even those cases that have gone beyond the type we have just considered, even those approaching the terminal stage, cases showing actual signs of true heart failure can be justifiably operated, in selected stages.

I have had some rather desperate cases of this character that I have operated upon against the advice of the family physician and they are all living and in comfort.

The characteristic and outstanding feature of Graves Disease (Exophthalmic Goiter Hyperthyroidism) is the fact that its complete elaboration takes place within a relatively short space of time, and the case when first seen presents usually a complete clinical picture. All the features of the disease are outstanding and present. In the hyperthyroidism of Graves' Disease, surgical procedures are directed to diminish the actual amount of thyroid tissue by removal of varying amounts of hyperplastic tissue.

In the hyperthyroidism, due to exophthalmic goiter, iodine should never be administered until the patient has decided to submit to an operation and be confined to a hospital. When the patient has had sufficient rest in bed iodine should be given approximately ten to twenty-one days before the day decided upon to operate. The iodine is used to counteract the terrific and sometimes fatal reaction which patients have 24 to 48 hours post-operatively, even after the most perfect thyroidectomy.

#### TREATMENT OF IODINE HYPERTHYROIDISM

For several years, however, the promiscuous use of iodine in the form of table salt, etc., in the treatment of goiter by certain physicians and persons of no medical knowledge, has given rise to a condition to which the name Iodine Hyperthyroidism has been applied.

Within the last year several cases have come to our clinic and it has only been with the greatest of care that these patients have been saved and one case died before we were able to readjust the treatment.

Any type of goiter may undergo a change, even when in quiescent condition, if iodine is not intelligently given.

Although I used the words "Simple or Endemic" at times, this is not an endemic locality for goiter and a wholesale use of this drug is decidedly a reprehensible practice. We, in this vicinity, must treat each case individually and as I have already said, "Know when to use, what and how to use, the drug indicated."

#### SUMMARY

In conclusion, I will sum up the points upon which I have tried to lay stress as follows:

- 1 Simple goiter is not a hypertrophy but essentially a degeneration of the thyroid gland. The gland is not overactive, but underactive.

- 2 Whatever may be the connection between iodine and the thyroid gland there is no reason for believing that a lack of iodine has anything to do with the causation of goiter.

- 3 It is quite certain that, at least in the majority of cases, the disease is produced through the agency of drinking water.

- 4 That there is a frequent co-existence of goiter and tuberculosis in the same patient. And diagnostic difficulties are many at times.

- 5 The essentials should be thoroughly understood and carefully considered each time treatment for a hypothyroid patient is contemplated, and it should be briefly explained to the patient in order to obtain full cooperation.

- 6 That treatment of simple goiter, if possible, should be started before birth, and treatment of adenomatous goiter before hyperthyroid symptoms have markedly progressed, and that iodine in this particular variety should never be given. That exophthalmic runs a rapid course and should be recognized as soon as possible and the proper surgical measures observed.

- 7 That it is an extremely serious practice to treat adenoma of the thyroid with iodine, especially after 25 years of age, for fear of producing iodine hyperthyroidism, and that iodine should only be given to an exophthalmic goiter case when the patient has given consent to be operated upon and has entered the hospital.

## END RESULTS OF PROCIDENTIA OPERATIONS\*

By FRANK A PEMBERTON, M.D., BOSTON, MASS

**T**HIS is a report of the cases of procidentia operated on at the Free Hospital for Women, Boston, from 1909 to January 1, 1924, by seven surgeons. This period was chosen because the method used was worked out and standardized as nearly as it can be by 1909 by the chief surgeon, W. P. Graves.

Procidentia is a degree of prolapse in which the cervix of the uterus protrudes from the introitus or the whole uterus comes outside. The examination of the patients in this series does not always reveal which degree of procidentia was present so we have not tabulated them accordingly. We have included only the cases operated on because of lack of time to read the report of the others. Many were refused operation because of poor general health, diabetes, and other diseases.

The fundamental idea of the procedure is to remove diseased tissue, to build up a strong vaginal support, and to suspend the vagina at a height which will be as near normal as possible. By 1909 it had become evident that vaginal or abdominal support alone was not curative in enough cases.

The cervix is amputated, if it is hypertrophied, by Hegar's method. This removes diseased tissue and gives a higher insertion of the bottom of the bladder on the cervix, so that it is drawn up well by the abdominal operation. The cystocele is carefully done, the attempt being to find the edges of the unstretched fascia on the sides and to suture them together with buried catgut. The perineum was done by Emmet's method during the early years, but for several years a modification of Clark's method by a central triangular denudation with uncovering of the levator muscles higher up on the sides has been used.

The ideal of the abdominal operation is to pull the vagina up so that it will be taut. The procedure chosen depends on how far up the uterus can be drawn. If the fundus comes outside the incision a supravaginal hysterectomy is done. If an amputation of the cervix has preceded this, about an inch of cervical tissue is left. The broad ligaments are sutured to this stump, the bladder flap drawn over its top, and the whole sutured to the abdominal wall an inch or two above the pubes by two silk sutures passed through the sides of the cervical stump and the peritoneum, muscle, and fascia of the abdominal wall, one on each side of the incision. If the uterus can only be drawn up to the abdominal wall, it is attached to it by two silk sutures passed through the

fundus in women who have had the menopause. This may be reinforced and the space between the two silk stitches obliterated by a catgut stitch passed from side to side through the peritoneal edges of the incision and the fundus of the uterus. In cases complicated by fibroids, and some others, a supravaginal hysterectomy is done and the fixation used only when apparently necessary, the support of the broad ligaments being depended on in the rest. In younger women a modified Olshausen suspension is usually done. In this series the Simpson, Mayo, and rarely the Baldy suspensions were used a few times according to the ideas of the operator.

If the procidentia is a large one and the general condition of the patient not good it has been customary to divide the procedure into two operations. The first one consists of the amputation, usually the repair of the cystocele and the appropriate abdominal operation. The second one is done two weeks or more later and comprises the cystocele if it has been left, and the perineum. One fault in doing this is that if the patient is allowed to go home after the first operation she may fail to return for the second, and others may refuse it. As a result we have a number who have not had the whole plastic. In most such cases the perineum is the part not done.

Also we find some of these women have diastasis of the recti muscles and umbilical or ventral hernias which we repair carefully.

In some it has been thought wise to use the Moschowitz operation of obliterating the posterior cul de sac to assist in curing the rectocele. In young women who have borne many children sterilization has been advised and carried out, usually by excising the tubes from the uterus.

### Number of Years After Operation

		Well Cases			
Year	Cases	Year	Cases	Year	Cases
1	12	7	13	13	7
2	16	8	13	14	4
3	14	9	7	15	4
4	25	10	11	16	1
5	21	11	6	17	2
6	11	12	3		

The patients were asked to report by letter as to whether they had had any recurrence of their prolapse and any bladder or other symptoms and to report for examination if possible. Sixty-four per cent were examined by members of the staff and letters were depended on for the rest. These reports have been obtained at various times and are one or more years after operation. Those classed as well are without symptoms and, if examined, the vagina

\* Read at the Annual Meeting of the Medical Society of the State of New York at Niagara Falls, N. Y., May 11, 1927.

has been found to be well held up and there is a good result for the plastic work

#### Number of Years After Operation Relieved Cases

Year	Cases	Year	Cases	Year	Cases
1	17	5	4	9	2
2	2	6	6	10	2
3	3	7	3	11	2
4	3	8	2	12	1

The causes of symptoms in the 47 relieved cases were as follows

Prolapse, 5, Rectocele, 12, Cystocele, 16, Hernia in scar, 11, Miscellaneous, 5 (2 patients had both hernia and cystocele)

The degree of recurrence is slight in any case, because if the patient had symptoms which interfered with her daily life the case was classed as a failure

There are too many hernias in the scar, but these operations were done on poor people who many times cannot abstain from work after operation for as long as they are told

to and who have abdominal walls badly stretched out by many babies

An analysis of the failures is always the most interesting part of such a compilation as this. The average age was 47, so age had no influence

Three were due to trauma. One began hard work in a factory after the operation and had a recurrence in less than a year. Two had recurrence after bad falls, one 8 years and one 10 years after operation

Three were apparently due to pregnancy. One of these had a Baldy suspension and plastics, became pregnant 2 years after operation and had a miscarriage at 4 months, which was followed by cystocele and retroversion. Another became pregnant in 9 months after leaving the hospital, had a normal delivery, a recurrence which was operated on, and another recurrence after that. The third had a complete operation, a baby, a recurrence and a hernia in the scar

#### PROCIDENTIA

Whole Number of Cases	496	Average Age—48.5
Reports obtained from—	247	Average Age—49.7
Well	170—68.8%	Average Age—46.0
Relieved	47—19.0%	Average Age—48.0
Failure	21—8.4%	Average Age—47.0
Deaths in 496 cases	9—1.8%	Average Age—58.0
Married	239	
Parous	237	Average number of children, 3.8
Nulliparous	2	
Single	8	
Total nulliparous	10	
Normal labors	135 patients	
Instrumental labors (one or more)	102 patients	
Operation done before menopause		140
Operation done after menopause		102
Not noted		5

#### TYPES OF OPERATIONS

	Total	Well	Relieved	Failure
Complete Plastic, Hysterectomy, Fixation	76	67%	22%	7%
Partial Plastic, Hysterectomy, Fixation	31	61%	22%	12%
Complete Plastic, Hysterectomy, Fixation	13	61%	15%	7%
Partial Plastic, Hysterectomy, Fixation	6	Not enough cases		
Complete Plastic, Fixation or suspension	93	75%	16%	7%
Partial Plastic, Fixation or suspension	28	64%	17%	7%

#### Patients having two stage operation—

Total	94—38% of total number
Well	66—38% of well cases
Relieved	19—40% of relieved cases
Failures	7—33% of failure cases
Deaths	2—22% of deaths

#### Associated Operations—

Approx. Rect	49
Moschowitz	9
Hernia	15
Complete Tear	3
Sterilization	8
Gall bladder	2

#### Pregnancy after operation—

No recurrence after labor	2
One child	1
Two children	1
Recurrence after labor	3
One child	2
Miscarriage	1

#### Complicated Pathology—

Silk Stitch Sinus	9
Fibroids	28
Adenomyoma	2
Hydrosalpinx	1
Parovarian cyst	1
Ovarian cyst	5
Large	2
Dermoid	1
Malignant	1
Retention	1

One was due to the technical fault of making a ureteral fistula in doing a Moschowitz operation, which caused sepsis necessitating several operations

In the one the operation was primarily for a 64-pound ovarian cyst so that only a fixation was done to save time. She has been comfortable for 10 years with a pessary

Another patient had ankylosis of one hip so plastics could not be done. The fixation proved ineffective, and she had a recurrence with a hernia in the scar

A hemorrhage from the vagina after going home probably meant sepsis in the stump of the cervix which was suspended, so the tenth patient in this series had a recurrence

Four cases had incomplete operations, some step in the plastic being left out in each. One of them was a nulliparous woman. One recurred in a few months, one in 2 years, and one after 13 years

Seven had satisfactory complete operations. The recurrences came after a few months in one, 2 years in another, 3 years in the third, 5 years in the fourth, 8 years in the fifth, and the time was not noted in two

It appears then that in 7 cases there was no apparent cause for the failure, 4 may have been due to incomplete operations, 2 to technical faults (sepsis and ureteral fistula) and 8 to unavoidable complications if we do not advocate sterilization of all patients with procidentia

There were 9 deaths and no autopsies. The average age was 58, which is about 10 years higher than the general average as would be expected. Seven had a one-stage operation, and 2 the two-stage. Five deaths occurred 2, 3, 5, 16, and 30 days after operation and seemed to be due to circulatory failure. Two had pneumonia and died on the fourth day, and two had emboli, dying on the first and thirteenth days. All patients entered the hospital three to seven days before operation for observation and preparation, and these all seemed to be average risks before operation

The tabulation speaks for itself largely. It is interesting that there should be 10 patients

who had never been pregnant, their condition being due to poor, unelastic tissues. In three of these the operation gave relief only and one was classed as a failure

In the Types of Operation, a complete plastic consists of a suitable operation on the cervix or none if it is not indicated and a repair of the cystocele and perineum. Partial plastic means that either the perineum or cystocele or both were not repaired. This may have been due to the second part of a two-stage operation not being done or it was thought unnecessary by the surgeon. The table shows that the complete plastic is the more reliable procedure, as would be expected. The fact that more patients were cured by the complete plastic and fixation or suspension is probably because they were not as bad cases as those treated by hysterectomy and fixation. The failures are pretty evenly divided, the highest being among the worst cases with the incomplete operation. Other than that it would appear that the type of operation was well suited to the particular case

In regard to the associated operations, we feel that approximation of the recti muscles when they are separated is an important step, because it gives a stronger abdominal wall, better support to the viscera, and relieves backache. This backache is due to poor posture which is not relieved entirely unless the protruding, pendulous abdomen is drawn in. It is done by enlarging the wound upward as far as necessary, down to the fascia and reduplicating the fascia by figure of eight sutures passed through it at the edges of the recti muscles. These sutures are usually No 2 c c g, occasionally linen or silk

The Moschowitz operation is done when there is a particularly deep posterior cul de sac

As regards Complicating Pathology the sepsis that occasionally occurs around the silk fixation stitches is a nuisance but as soon as the suture comes out the sinus closes. In some instances the silk is passed by vagina

It is well known that cancer of the cervix is not found with procidentia and in this series of cases no cancer of the fundus appeared

## ORGANIZED MEDICINE ON LONG ISLAND

Five addresses before the Second District Branch of the Medical Society of the State of  
New York, November 9, 1927

### KINGS COUNTY

By THURSTON S. WELTON, M.D., BROOKLYN, N. Y.

**I**N review since the last meeting of the Second District Branch the year shows progress in the same general lines of community activity and professional work.

The keynote in our public relations is participation rather than mere cooperation by endorsement, or approval of someone else's activity.

The Brooklyn Health Council—a joint committee created by the Brooklyn Chamber of Commerce in whose quarters we are meeting tonight and the County Society—considers general health problems and needs.

The Brooklyn Visiting Nurses Association for whom the County Society, through its Public Health Committee, acts as a medical advisory board.

The Brooklyn Maternity Center Association, whose Directress is making the field visits for the Public Health Committee in its study of the costs of maternity service.

The Nurses Official Registry, on whose Board the Nursing Committee of the County Society has representation.

The American Social Hygiene Association and our Public Health Committee are conducting over a three-year period a study of syphilis control in private practice for comparison with public clinic results.

The Brooklyn Tuberculosis and Health Association makes available \$1,000 per year for activities along lines of preventive medicine within our professional ranks. In addition joint activities as in health examination work, public lectures and the like are participated in. The President of the Society is an ex-officio member of the Committee. Support of the library of the Society by the provision of material on tuberculosis is another evidence of the team-work.

The Associated Out-Patient Clinics, now a committee of the New York Tuberculosis and Health Association, functions in Brooklyn with the guidance of our Public Health Committee and aids in the support of that Committee by an annual contribution of \$3,000. Dr. Charles Prest, by his friendship, interest and also as a member

of the Society, has been of more than material aid.

Our Milk Commission annually certifies over 6,000,000 quarts of milk and is in its twentieth year.

Our Committee on Illegal Practice finds that there are still things to be done. We are trying to make the Webb-Loomis Bill work. Dr. Joseph Behan has been the right man for a thankless job.

The foregoing illustrates our attempt at participation. Various other civic activities are under way, for instance, at present we are providing twenty lectures for the Y. M. C. A.

Within the professional ranks we are continuing along proven lines.

The Friday lectures are continuing 20 a year. The audiences are still large, and the interest keeps at a high pitch.

This week we present the 115th lecture. Paul B. Hoeber, Inc., medical publishers, late last spring brought out the second volume of these practical lectures.

Graduate courses in medical education still continue. Dr. Charles Gordon, one of the founders of the Brooklyn Idea in graduate medical education and who served the State Society so brilliantly in this work, is the present Chairman.

Never in our history have we had such attendance records at our monthly meetings. This reflects little credit on the President, but proves the point that the time was psychologically opportune to attract great numbers.

Associate membership of laymen interested in scientific medicine and the work of the Society has become an accomplished fact.

Last spring we gave 6 lectures by members for the general public.

Last, we still maintain the library—the first public medical library in New York or Brooklyn—now a library of upwards of 110,000 volumes, necessitating the movement, which has gained great momentum and seems to be shaping up as a reality, of a new \$1,000,000 home.

### QUEENS COUNTY

By FRANCIS G. RILEY, M.D., JAMAICA, N. Y.

**A**S SPOKESMAN of Queens, I have two topics on which I wish to speak. First of these is Graduate Medical Education. If imitation is the sincerest form of

flattery, Kings can be justly proud, for we of Queens as well as others, have appropriated bodily the scheme worked out by your original Committee on Graduate Edu-

cation, and during the two years in which we have carried on this work in Queens we have not been able to improve upon this plan. Our work is divided into two divisions: first, our Friday afternoon talks, and second, our Clinical Courses given in the various hospitals in the Borough. The afternoon talks are held in Jamaica as the most convenient place of meeting for a majority of men in the Borough. Our average attendance is about 10 per cent of our total membership. We find that a majority of the men are interested in the major divisions of practice and are inclined toward the Surgical. The minor specialties are neglected by the majority for such subjects as Surgery, Gynecology, Obstetrics and Pediatrics. I suppose that this is a condition not local in character and not amenable to any correction through the efforts of our Committee.

Our Clinical courses given at St. John's Hospital in Long Island City, Flushing Hospital in Flushing, Queensboro and Jamaica Hospitals in Jamaica and Rockaway Beach Hospital in Rockaway Beach have been offered on a variety of subjects in each hospital so that men in all parts of the Borough may take advantage of them. They have been on the whole well attended and many of the courses oversubscribed.

My second topic is that of the relation of the County Medical Society to lay organizations that have for their object the promotion of public health. I am aware that this is a controversial subject, with its proponents and its opponents. Personally, however, I feel that the medical profession can receive great help in its fight for better community health from such organizations when the proper spirit of cooperation is evidenced by all parties concerned. The Medical Society of the County of Queens has for several years had the whole-hearted assistance of the Queensboro Tuberculosis and Health Association in such matters as Graduate Education, the establishment of Clinics for the early recognition of tuberculosis and heart disease. Each year our relations have become more cordial. I feel that this is the means by which the medical profession can reach the public as in no other way. The Secretary of the Queensboro Tuberculosis and Health Association is an active member of our County Society. It has on its membership and its Board of Directors a number of other members of the County Society. The interests of both organizations are furthered and protected and, what is more important under this ideal arrangement, the public has benefited to the greatest extent.

## NASSAU COUNTY

By LOUIS A. VAN KLEECK, M.D., MANHASSET, N. Y.

**T**HE practice of medicine in Nassau County is rapidly changing as rural conditions give way to urban. Owing to the great overflow of people from New York City, the population of the County has doubled during the last five years. Yet the Nassau County Medical Society has continued the leadership in civic medicine that it has always taken, and has actively promoted every public health project that has a practical value.

The Society made an intensive study of the hospital situation in 1922, and found that there was less than one bed available for each one thousand of population. Its committee made a report on the localities in which new hospitals may be located to advantage, and its suggestions have been heeded in their establishment.

The Society has also insisted on the requirement that every physician on a hospital staff shall be a member of the County Society.

The County is in great need of a hospital for the care of chronic cases, especially those of advanced cancer. There is also a great need of a hospital for the treatment of communicable diseases. The County Society is promoting both of these projects. Provision for the treatment of venereal diseases is also receiving attention.

Tuberculosis work is centralized in the County Sanatorium under the leadership of Dr. A. J. Davis, Superintendent. The physicians are co-

operating with the sanatorium physicians and the staff of field nurses in the promotion of diagnostic clinics in the home visitation of cases. The Society is well satisfied with the administration of anti-tuberculosis work.

The Nassau County Medical Society meets once a month and precedes each session with a social supper which brings the members together on friendly grounds. During the winter the Society also has a weekly lecture on some subject that is chosen by means of a questionnaire of the members.

The Society recognizes the need of a county health department, especially since there has been an epidemic of forming new villages each of which is an independent health unit. There are now about twenty small villages in which public health work is on too small a scale to be effective. The County Society voted to promote a county department of health about eight years ago, but its establishment was delayed because a proposed county charter embodied the plan. The members of the County Medical Society now recognize that the need for a county health unit is more acute than ever.

It may be truthfully said that the Nassau County Medical Society stands for the leadership of physicians in all phases of the practice of medicine.

## SUFFOLK COUNTY

By W H ROSS, M D, BRENTWOOD, N Y

**W**HATEVER any County Medical Society is doing to meet the present day medical problems arising from the changing conditions of modern life cannot be reflected better than by what they do in reports and discussions at their meetings. It cannot be shown in any better way just how the medical profession undertakes to safeguard general health (call it public health if you like) in addition to curing disease. I have chosen to tell you something of the annual meeting of the Suffolk County Medical Society held two weeks ago in order to show you what it is doing in civic affairs and thus to pass in brief review the work of Suffolk County in civic medicine for the last year. I cannot draw on imagination in this because I am dealing with facts.

I have in my hand the program of the meeting of October twenty-seventh. There were reports on public health, children's clinics, general hospitals of the county, the need of more beds for the chronic indigent cases, report of the Publication Committee, of the librarian, the Legislative Committee, the anti-tuberculosis work in the county, the official public health work by the district health officer and the district supervising public health nurse, the County Tuberculosis and Public Health Association, child welfare work, reports from the four district medical societies of the county and then a scientific program of a five-minute clinical report from each of the four general hospitals and a moving picture of the pathology of syphilis of the heart and of aneurism.

I wish to add a reference this year to the report that I made a year ago. We continue to publish our monthly News Letter—fifteen hundred copies—thirteen hundred of which we sell to the Suffolk County Tuberculosis and Public Health Association for distribution. We do not farm out this publication nor do we publish the medical and health organization news and the allied medical and welfare activities in the county. We indulge in editorial comment which frankness gets us into moderate trouble once in a while and gives some of us mental exercise in the art of defense. Several of these reports offered constructive suggestions for the future and two showed how active the doctors are in child welfare and public health work and that about sixty per cent of the physicians of the county were performing some amount of public health service. A report of this meeting will occupy an entire issue of the *Long Island Medical Journal* and will show in a way that makes unnecessary my going into further detail, the activity of the Suffolk Society in civic medicine.

I think that I have indicated enough to show

that we are in the vanguard in medicine and that we are keeping up with the other counties of this District Branch. In one respect we believe that we may be leading in that there is not a single organized lay health effort in Suffolk County not dominated entirely both in program and in administration by medical men and none not directed by the County Medical Society. Even the public health committee of the large active flourishing Long Island Chamber of Commerce has upon its membership two men of the four county societies of this District Branch and some civic minded men are on the Chamber's board of directors.

The evolution in medicine including prevention of disease goes steadily forward. Passing the year in review the Suffolk County Society has met its obligations and has made some advance in safeguarding man from the hazards of modern life. Among other things the Suffolk County Society has studied hospital management, the number of beds available per thousand of population and published reports. The Society did this because it discovered that the average layman was more interested in hospitals than he used to be because he appreciates more the service that they can render.

The Society has done much to advance staff organization in hospitals for the purpose of critical review and analysis of hospital work and better standards of practice. It has done something to make the county hospitals teaching centers and places from which radiate the forces that advance standards of medical practice and that continually give a post graduate course in medicine to its staff.

The Society's plans for the future are to continue the activities that are producing results, solving present problems, and to aid new things as the evolution in medicine shows the way. A main objective this year is to establish a County Health Department because health is no longer the problem only of a local neighborhood. How soon the conviction that a County Health Department is needed and will find its expression in the establishment of one depends, we believe, upon the active leadership of the County Medical Society and all the lay aid that we can have from every source.

We believe that doctors only have the ability to choose between theoretical and practical activities in health matters. The development of public health and the practice of the prevention of disease is a doctor's game. The responsibility rests with physicians.

Unaided financially Suffolk County has reduced its tuberculosis death rate to 44.7 per hundred thousand of population—excluding non-resident population just by exercising leadership in med-

ical and allied affairs and in having a program and in steadily pursuing it year after year by examining contacts. We have listed now 1,728 cases of tuberculosis in a population of 143,000—or nearly 12.5 per thousand.

We are ready to report to the State Society that Suffolk County began to grasp the new obligation that everyone sees now resting on the medical profession ten years ago when we bought

a site for a tuberculosis hospital and then canvassed the county in an election to carry a referendum vote, and won it against decided opposition, and that we have grown in a sense of understanding our professional obligations in addition to practicing curative medicine, and that we caught enough of the spirit of it all so that we saw the need of leadership while there was yet time to assume it.

## THE RELATION OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK TO THE PHYSICIANS OF LONG ISLAND

By JAMES E. SADLIER, M.D., Poughkeepsie, N. Y.

President of the Medical Society of the State of New York.

**M**Y addresses before the other District Branch meetings have been on the general subject, "The Aims and Activities of the Medical Society of the State of New York." My subject tonight is more concrete, and is "The Relation of the State Society to YOU—Physicians of Long Island." This directness of address has been made possible by your program which is unique in that it is devoted entirely to organized medicine. Moreover, the specific reports from each constituent County Society afford the occasion for a comment by the official head of the State Medical Society. I was aware of the advanced accomplishments of the four County Societies of Long Island, and when I met the representatives of the Societies last June to plan for this District Branch meeting, I made the suggestion that the Committee invite the physicians from the whole eastern end of the State to come here and see what the doctors of Long Island are doing in their Medical Societies.

It is a pleasant duty of the President of the State Society to go over the State and meet the members at home, and see what they are doing. I have found that curative medicine—the treatment of established disease—is being done increasingly well all over New York State. New hospitals are being built, and old ones enlarged, clinics are being established, and the staff meeting has become a standard institution whose omission marks a hospital as backward. The reports given tonight by the county representatives show that the doctors of Long Island are equaling the record of those of any other part of the State in curative medicine, but they also show that the Long Island doctors have been peculiarly successful in the practice of preventive medicine.

The practice of medicine is changing, and no doctor can now afford to limit his practice to the cure of established diseases—he must be ac-

tive in seeking to prevent sickness and disease. Physiological processes pass insidiously into the pathological and health fades into sickness just as the green leaves change into the livid hues of autumn. It is the function of the physician to note the change from the normal to the pathological—to guard the people against designing alarmists, and yet promote all measures for detecting approaching sickness and warding off disease.

Lay organizations have often appropriated the fields of preventive medicine, and often it has been with the consent of the medical profession. But the doctors of Long Island have recognized their civic duties early, even before the wave of enthusiasm over preventive medicine had been raised by lay health organizations. It is refreshing to hear from the reports how the lay health organizations of Long Island work for the doctors, instead of the doctors working for the lay organizations.

The doctors of New York State recognize the vital need for lay organizations in public health work, let no one think otherwise. The peculiar field of the lay organizations is twofold: first, to add to the facilities by which physicians can practice better medicine, and second, to stimulate the demand of citizens for the services of the physicians along both curative and preventive lines. To provide doctors with hospitals and nurses and other means for the practice of medicine is as important as the actual ministrations of the doctor. There is glory enough for all. In fact, physicians shrink from publicity. The people need to deal with facts rather than the display of emotion, and physicians need to guide the lay organizations so that they may function along practical lines. The physicians of Long Island have shown how the representatives of the medical societies may exercise a gentle and friendly leadership over the lay health organizations.

## COURT EVIDENCE OF INTOXICATION

The legal aspects of court evidence in cases involving the question of intoxication are discussed by Mr. Stryker, the legal counsel of the Medical Society of the State of New York, on p. 1321 of the legal department of this JOURNAL. The court usually relies on the physician to give testimony whether or not the accused is intoxicated. The opinion of any one regarding the intoxication of a person, is admissible in court, and much more will the opinion of a testifying

doctor be admitted. Both may be cross-examined, but the opinion will not be stricken from the record because the witness cannot describe a test or symptom that is a sure proof of intoxication.

Mr. Stryker's article will enable the physician to testify with confidence regarding the soberness or intoxication in a case such as that against an automobile driver in which a slight degree of mental incoordination may be fatal.

## A PROGRAM FOR A DISTRICT BRANCH MEETING

The theory on which the eight District Branches of the Medical Society of the State of New York is founded is that each one is a geographic group whose interests and associations are similar. The number of members in the groups varies from about 400 in the Fourth District, which is located in the northeast section of the State, to over 4,800 in the First Group, which includes the boroughs of Manhattan and the Bronx in New York City. The immediate interests of the members of the groups vary as widely as the physical geography of the sections, and the problems of mountainous Clinton County on the Canadian border are not those of Manhattan with its canyons teeming with cliff dwellers. The District Branches enable the members to meet together and discuss their common interests, and the President of each Branch is a member of the Council of the State Society and brings to it an intimate knowledge of his own District, and especially of the activities of the County Medical Societies. The District Branches, therefore, are connecting links between the County Medical Societies and the State Medical Society, and their functions are largely advisory. Their officers are available for the assistance of the leaders of the County Societies, and they bring to the State Society a record of the activities and sentiments of the members of the County Societies.

The annual meeting of the District Branch affords the opportunity for the representatives of the County Societies to report on their accomplishments and aspirations, and to meet the officers of the State Society both socially and officially. The program of the meeting will therefore reflect the sentiments of the members of the constituent societies. A period of four years of attendance on practically all the District Branch meetings, thirty-two in number, makes possible the construction of a composite program which shall embody the best features chosen from all. While no meeting may conform entirely to the model, yet every feature of the ideal program has been in concrete operation in some meetings.

One feature on which there has been almost a unanimity is that the meeting shall consist of three parts:

- 1 Administrative
- 2 Social
- 3 Scientific

The administrative section is devoted to Medical Society problems—those which are handled by organizations rather than by individual physicians. This part of the program will naturally be in three parts:

- 1 A survey and report of the activities of each County Society by its president, secretary, or other officer
- 2 A report on the District by its president
- 3 A discussion of the policies of the State So-

ciety by its president, with special reference to the particular needs of the District.

A certain length of time will be assigned to each report, and that period will be strictly observed.

How shall the length of the period be determined? There is only one way—have each speaker write his report and send a copy to the president of the District Branch and another to the president of the State Society for their use in preparing their own written addresses. With these addresses at hand, the program committee can assign a time to each speaker with confidence that it will be observed. When a speaker writes out his remarks, he will say all that he wants to say, and will put it in clear, concise language and in an attractive style. If the speaker is good at off-hand talks, he can inject humorous side remarks to delight his admirers.

Moreover, a written manuscript is valuable from an editorial point of view. Speakers frequently object to being quoted literally, and to the editor's paraphrase of their remarks. A manuscript will promote the peace of mind of both the author and the editor. It will also ensure the author recognition in the JOURNAL.

The embarrassing situation may arise that the president of the County Society may think he has nothing to report. There is no society that has nothing at all to report. Every society has something along the line of either accomplishment or aspiration. The mere fact of making a survey of the county is a big step toward undertaking some tangible activity. When the president of a County Society reports a need along a certain line, he may be sure that he can receive the assistance of the officers of both the District Branch and the State Society. One of the great objectives of the officers of the Medical Society of the State of New York is to secure originality of action by the local societies. They are interested in the aspirations of County Societies even more keenly than in their accomplishments, for aspirants require assistance.

The peculiar field of work of County Medical Societies is the practice of public health and civic medicine, and the assumption of their rightful leadership in all lines of medical practice is the newest development among organizations of physicians. The president of every County Society numbers health officers among its members. The president often comes in contact with lay workers, such as those in the County Tuberculosis Committees, Parent-Teachers' Associations, and Public Health Nursing Societies. His report can tell the relations of the doctors to these organizations, and outline plans for future co-operation.

How long should the administrative part of the program last? If there are six constituent county societies, an assignment of five minutes to each

—which is enough—will occupy thirty minutes. The president of the District Branch and the president of the State Society will each require fifteen minutes. Thus a minimum time of an hour will be required for the administrative part of the program.

When should the president of a District Branch begin to prepare a program? Two or three months before the meeting, or long enough in advance to inform each speaker what is expected from him and to give him time to prepare his report. A program will not develop and run itself. The president has an allowance for expenses, such as clerical hire, for arranging his program and conducting the meeting. He can secure the reports from the County Society officers if he goes after them, and then, of course, he will prepare his own report and inform the president of the State Society about the contents of all the reports.

The social part of the program is of as much importance as that of the administrative and scientific sections. Getting acquainted with one another is one of the great attractions of District Branch meetings. A reception committee is a necessary adjunct on every program. A conspicuous ribbon will distinguish each of its members, and will be his introduction to each newcomer and his authority as official handshaker. When a physician enters who is a comparative stranger, the committeeman may properly inquire, "Where are you from? Are you looking for any particular person? Can I introduce you to some member in whom you will be interested?" A member who is received in this hearty way is likely to come again.

The reception committee will also keep a roster of those present. The president will use it in making up his plans for next year's meeting.

A social dinner is an important part of a program. Let it be served on the minute that was advertised, or even earlier. A hungry member is impatient and irritable for physiological reasons that doctors, of all people, should respect. Feed this member, and he is at once receptive to new ideas.

After a dinner, there is always difficulty in dragging groups of members apart. Meeting their fellows socially is one of the attractions which promotes a large attendance. It is one of the important duties of the members of the reception committee to introduce the lone, diffident member into animated groups where he may feel at home and enjoy himself.

A scientific program has a place in every District Branch meeting. The members are interested in what they do in the course of their daily work. They see a dozen or more sick people every day, they take an active part in some form of public health work once or twice a week. The great development of graduate medical education during the last three years is evidence of the desire of physicians generally to learn the most modern methods of diagnosis and treatment.

These two facts are to be kept in mind in making a scientific program—first, the great majority of physicians are general practitioners, and second, every specialist needs to know general medicine. What kind of paper appeals to the members of a District Branch? It is one that is an index to a subject rather than its complete presentation in all its details. For example, popular papers have been given on the following topics:

The acute abdomen, and what the doctor is likely to find in it.

Newer operations on the nervous system.

Modern gynecological procedures in office practice.

These papers were accompanied by charts and lantern slides, and demonstrated what a doctor should look for rather than how to carry out the details of an examination. The group of medical teachers who are being discovered and developed is constantly being enlarged as doctors trained in literature and research are becoming available.

Shall there be a discussion of every paper? There is no occasion for a discussion of any of the three subjects that have been quoted. A discussion belongs to a paper that sets forth a new discovery, or method, or plan, to an audience of the peers of the speaker, but a discussion is likely to be an anti-climax when a speaker drones on after a brilliant presentation which is designed to arouse the physicians to desire to know more about a subject, and to have it consciously in mind in the sick room.

Another fact is to be borne in mind by those who prepare the programs of District Branch meetings—the doctors come late and go away early. A few come especially to hear the reports of the officers of the medical societies. Most come to hear a scientific paper. All are glad to meet their medical brethren.

The members are always impressed with a program that applies to their particular locality, and they will praise the speaker who gives a clear, concise paper on any subject.

---

### FAITH HEALING

The Rev. Dr. John Roach Straton, Pastor of the Calvary Baptist Church, West 57th Street, New York City, has been conducting special services during the past month for the purpose of healing the sick. The method used is literally that

prescribed in the Bible in the Epistle of James Chapter 5, verses 14 and 15 which read:

"Is any sick among you? Let him call for the elders of the church and let them pray over him, anointing him with oil in the name of the Lord,

and the prayer of faith shall save the sick, and the Lord shall raise him up, and if he have committed sins, they shall be forgiven him"

The Bible and the church have always stood primarily for healing the soul, and secondarily for healing the mind and the body in so far as they affect the soul. Faith and prayer are the two means which the church uses, and which are approved and encouraged by the very great majority of physicians, both Catholic and Protestant, Gentile and Jew. The faith of the patient is at the foundation of all healing. The physician seeks to arouse the sick to have faith in his ministrations and in the healing power of nature. Those piously inclined will personify the healing power and call it their personal God, and also the power of evil, and call it Satan. The majority of physicians, whether they be churchly inclined or not, will be content to implant faith in the hearts of the sick without defining too closely the object of that faith.

Faith enters into every act of healing. The man with a broken leg needs faith to enable him to lie quietly in bed during a month of reconstruction, and to bring calm sleep during the long

night hours. The crippled boy needs faith to ignore the pain and stiffness of a chronic arthritis of the knee as he throws aside his crutches and walks. Faith itself is the means of healing the paralysis of a "shell shocked" soldier whose condition is due to a defect in his will power. Every physician seeks to inspire faith in his patients, and feels that he is a failure in the absence of evidences of that faith.

Dr. Straton, of Calvary Church, has an unbalanced program if he depends on faith alone to heal the sick who come to him. The Apostle James, whose method the pastor follows implicitly, insists on works as well as faith, and would doubtless utilize the healing work of the physician quite as much as the faith of the patient. It is difficult to determine to what extent, if any, pastor Straton ignores the physicians. The cases who seek him, like those who came to Christ, seem to have gone to many physicians without relief, and they will go back to their doctors when their infirmity recurs. At any rate the benedictory touch of the pastor can have no such damaging effects as the violent laying on of hands by the chiropractor.

## LOOKING BACKWARD

### THIS JOURNAL TWENTY-FIVE YEARS AGO

*Volume Two of this Journal*. The December 1902 issue of this JOURNAL says editorially:

"THE NEW YORK STATE JOURNAL OF MEDICINE with this number completes its second volume and we believe that this JOURNAL has lived up to all of its promises.

"From time to time various changes have been made, all tending to improve the character of the matter presented. It is as previously stated, the official organ of the New York State Medical Association, presenting matters of interest to its members in the shape of reports of the Council and Fellows, the news of its Annual, District Branch and County Association meetings, scientific contributions from its members, etc."

The present department of book reviews is still conducted with the same ideals as those stated twenty-five years ago.

"The column devoted to Book Reviews has received careful consideration and our aim is to present concise and careful criticism of the contents of the book, rather than a superficial résumé of the author's preface. These books are placed in the hands of active members of the Association who have made special study of the subject before them and hence all criticism is associated with intimate knowledge of the subject. Personalities will not appear."

The JOURNAL has not developed its news personals or its correspondence columns according to the plan set forth.

"An additional column of News Items has been

added and members are requested to send information of appointments and matters of social interest to the publication office before the 20th of the current month. Correspondence with our members is solicited, as we are especially desirous of impressing all our members that this JOURNAL is their own property and is run for their benefit and not purely as a business venture."

The following statement regarding advertisements is as important as ever:

"To defray the large cost of the publication of both JOURNAL and Directory it is necessary for us to have advertisements. The advertisements are most carefully considered, those that are ethical in the strictest sense only are received, hence our advertisers are in turn deserving of every consideration. If members will bear this in mind and mention the JOURNAL when communicating with advertisers, the latter will readily see the advantages of continuing their support."

The bureau of information and provision for visiting doctors have not worked exactly according to the editorial plan.

"Finally we again call attention to our Bureau of Information at our business office, 64 Madison Avenue. Not only will we cheerfully furnish any information in our power, but we will be glad to have our members, especially those who reside at a distance, make the office their headquarters. This invitation is extended to the wives of our members who may wish to rest, write letters, receive mail or meet their husbands here."

# MEDICAL PROGRESS

**The Pathology of Sea-Sickness**—After reviewing the theories that have been advanced to explain the cause of sea-sickness, G H Oriel (*Lancet*, October 15, 1927, ccxiii, 5433) describes carefully controlled experiments which prove that labyrinthine disturbances, if present, do not give rise to nystagmus or to alteration in labyrinthine tests. Other observations show that autosuggestion is not wholly responsible, as there is a distinct metabolic upset found in the pre-vomiting stage, as evidenced by hyperglycemia followed by hypoglycemia, increased ammonia excretion, and the presence of acetone in the urine. The administration of three drachms of glucose to more than 1,000 patients with sea-sickness gave results far superior to those obtained by the exhibition of the remedies ordinarily employed. When glucose is administered in a well established case acetone disappears from the urine, diuresis takes place, and ammonia excretion is lowered, with a corresponding increase in the total acidity in the urine. *Par passu* with the metabolic change there is an improvement in the general condition, and headache is abolished. The effect of the glucose in a well established case is much more dramatic than in the pre-vomiting stage, though it is also beneficial in this stage. Oriel has observed that if passengers can be persuaded to eat plenty of fruit and carbohydrates and to avoid fats, that they are never violently sick. The common error is to avoid food, which, of course, leads to early exhaustion of the glycogen reserve, acidosis is the inevitable sequel. It may be advisable to administer small doses of insulin with a large dose of glucose in those cases in which relief is not afforded by the administration of glucose alone. Though Oriel has not tried this himself, he hopes others will test its feasibility.

**Atropine and Scopolamine for Sea-Sickness**—Dr H E Kersten, who has made many sea voyages and has always been interested in the problem of sea-sickness, refers briefly to the relief given by certain forms of suspension apparatus which offset the rolling and plunging of sea craft. He then speaks of the action of atropine as a vagus paralyzant as recommended by various writers many years ago, on the theory that sea-sickness depends largely on excitation of the vagus through the semi-circular canals. Starkenstein has combined hyoscyamine with atropine since, despite the similarity of the drugs, the mixture is less toxic than the same weight of

atropine alone. Kersten sought to substitute scopolamine for hyoscyamine and in a sea voyage to the United States in 1926 provided himself with tablets containing the combination. On board were 19 travelers with severe sea sickness which had resisted the usual remedies. All were confined to their staterooms. It was impossible to get some of them to swallow the tablets so that suppositories had to be substituted. A second dose could follow only after the expiration of 3 or 4 hours, to avoid poisoning. The rest of the treatment was to have consisted of repose and careful diet, but so marked was the relief obtained that some of the patients left their rooms, completely relieved, and refused the second dose. Surprising to relate, the symptoms did not return during the balance of the voyage. The passengers were witnesses of the remarkable outcome of the trial and the author, for the first time in his long experience, saw sea-sickness yield completely to drugs. No failures are mentioned, although in some cases the results seem to have been more brilliant than in others. The present is only a preliminary statement, as the author will report his results in more detail at a later period.—*Munchener medizinische Wochenschrift*, September 16, 1927.

**Tribromethyl Alcohol in Psychiatry**—F Sioli and R Neustadt refer to the very recent trials of this substance as a rectal narcotic and to the numerous reports by clinicians of its use in several hundred cases in producing both surgical and obstetrical anesthesia. Since it procures sleep of some hours' duration it should also have a field in psychiatry and the authors have tested the drug for this purpose 53 times in 40 patients. The results were positive in all but 2 cases in which neither narcosis, sleep nor after-sleep resulted. In the great majority of cases the result was a narcosis, but in seven it was merely sleep. The effects were prompt and the sleep profound, like natural sleep. When the first effect was narcosis a secondary sleep followed. A ward of women patients which was usually noisy at night was astonishingly quiet and the stillness persisted into the following day. Despite the results of this wholesale trial the authors do not seem to have repeated it, evidently because narcosis as such was too vigorous a remedy. Attempts were made by modifying the dosage to tone the action down to simple slumber, but with small dose devoid of narcotic effects sleep was brief—1½ hours—and no after-sleep was

seen. The drug must be given by enema and a tenth of a gram per kilo of body weight was found to be quite safe. Neither local nor collateral ill effects were seen and it is probable that this kind of narcosis will be found well adapted to control any of the mental states attended by great excitement—*Klinische Wochenschrift*, September 24, 1927

### Hypertension of the Pulmonary Circulation

—This condition, not heretofore considered to be a clinical entity, is discussed by Eli Moschowitz with reference to its causes, dynamics, and relation to other circulatory states. Hypertension of the lesser circulation usually passes under the name of "pulmonary congestion," "right-sided insufficiency," or "arteriosclerosis of the pulmonary vessels." It is caused by any lesion that increases the peripheral resistance within the lesser circulation. The most common causes are mitral disease, especially mitral stenosis, emphysema, whether primary (senile) or secondary (asthmatic), infiltrating lesions of the lung (chronic tuberculosis with induration, bilateral pleural synechiae, chronic interstitial pneumonia, tumors), kyphoscoliosis, patent ductus arteriosus, and communications between the two sides of the heart. A sustained hypertension of the lesser circulation leads to arteriosclerosis of the pulmonary vessels, it may occur in much younger individuals than arteriosclerosis of the greater circulation. A "primary" arteriosclerosis of the pulmonary vessels, if it exists at all, is extremely rare. There is a mutual independence of arteriosclerosis of the greater and lesser circulation. This indicates strongly that no poison, bacterial or otherwise, metabolic product, or food substance can cause the lesion, because the same blood bathes both circulations. The physical signs of hypertension in the lesser circulation are those brought about by the compensatory mechanism. Of primary significance in the recognition of the condition are an accentuated second pulmonic sound, especially in the stage before decompensation begins, rise in venous pressure, swelling and tenderness of the liver, Graham-Steelle murmur, dilatation and hypertrophy of the right heart, dilatation of the pulmonary conus, dilatation of the superficial veins (especially pectoral), cyanosis, lowered kidney function, and infarction of the lungs. The one inevitable symptom is breathlessness. It is the disturbed function and not the arteriosclerosis that is responsible for the clinical syndrome. A transient (usually terminal) hypertension of the lesser circulation may occur in general vascular hypertension following mitral disease, when myocardial insufficiency develops and when there is an

associated emphysema. In left coronary disease it arises only after myocardial insufficiency sets in. So-called Ayerza's disease is not a disease but a syndrome due to any lesion that causes hypertension and arteriosclerosis of the lesser circulation. The constant relation of syphilis to this disease is not proven. Edema of the lungs may either follow or cause hypertension of the lesser circulation. It is caused by changes in the cardiac rhythm only after myocardial insufficiency arises. There is a likelihood that cirrhosis of the liver associated with cardiac disease is the result of increased tension within the hepatic area. This type of hypertension may also explain cyanosis in congenital heart disease—*American Journal of the Medical Sciences*, September, 1927, clxxiv, 666

**Cerebral Arteriosclerosis** — E. Guttmann enumerates the leading symptoms under this head which may be grouped in various ways. He mentions first a nervous group characterized by intense headache, vertigo and insomnia, and associated further with such psychic manifestations as memory failure and lowered efficiency. These may persist as such for years and with course not steadily progressive but marked by remissions. Another group may develop, which the author terms the "neurologic," but which might better be termed circulatory, characterized by cerebral hemorrhage, rush of blood, nosebleed, etc. According to the seat of the hemorrhage the symptoms vary extremely, although typical hemiplegia followed by death in 24 hours is a common termination. The third group is known as the psychiatric and the principal manifestation is arteriosclerotic dementia. At the outset, however, various types of insanity may be mimicked with manic and depressive manifestations, hypochondria, paranoid fancies, suicidal impulses, etc. In this third group belongs arteriosclerotic epilepsy. The brain is seldom involved alone, some other region of the body usually participating in the vascular changes. Under the head of disposition to apoplexy may be mentioned the pycnemic habitus of Kretschmer which disposes both to this lesion and manic-depressive insanity. In the clinic we also see an association of circular insanity and apoplexy. In addition to the usual causal factors the author mentions excess of cholesterol in the blood. Westphal has recently reported that all of his apoplectics showed hypertension. A reputed antagonist to excess of blood-cholesterol is potassium sulphocyanide, recently re-introduced into practice by Westphal—*Klinische Wochenschrift*, September 17, 1927

**Changes in the Type of Epidemic Encephalitis**—F Kreuser and E Weidner call attention to the fact that the original form in which this disease first appeared is not constant. At the outset we saw a hyperacute disease which showed a preference for the cranial nerves, while at present the beginning is chronic and insidious and the brunt of the disease is borne by the spine and spinal nerves. Cranial nerve paralyses have become rare and transient. It is as if the disease had crept down from the brain to the spine. We also see today various anomalies of the vasomotor system, and neurasthenic or psychopathic personality alterations, which are not to be confused with the psychic alterations originally reported in the case of children. The authors report seven cases, with ages varying from 17 to 42 years, which illustrate the changed type or atypical character of the disease. Despite what has just been said of an insidious origin, six of the seven patients came down originally with what appeared to be acute influenza but without suggestion of encephalitis. Associated with the headache, prostration and fever were such vasomotor symptoms as sweating, salivation, livid and cold hands and feet, etc. Motor phenomena were limited to tremor or tic-like spasms of the head and neck. Aside from this grippe-like onset the development of the symptoms was gradual. In one of the seven patients, a woman of 29, there was no grippe-like onset but the initial symptom was difficulty in swallowing. It was necessary to use the fluoroscope to exclude the presence of a swallowed foreign body. Severe cardiac crises developed with pain and tachycardia, a sense of impending death, and many hypochondriac sensations. These attacks of palpitation and dysphagia were also present in other patients of this series. It is not entirely clear, from the character of the symptoms, how the authors were able to make the diagnosis save by exclusion, for there was hardly anything suggestive of encephalitis.—*Deutsche medizinische Wochenschrift*, September 9, 1927

**Mucous Colitis Due to Food Allergy**—Edward Hollander, writing in the *American Journal of the Medical Sciences*, October, 1927 (CLXXIV, 4) describes five cases of mucous colitis caused apparently by hypersensitiveness to food proteins. In these cases the treatment usually employed, consisting in the removal of foci of infection, colon irrigations, acidophilic bacterial implantation, correction of ptosis by mechanical support, bland protein diet, and sedative medication, failed to give more than temporary relief. The clinical picture disappeared only after the omission of foods to which the patients were sensitized, and it re-

appeared when the foods were ingested, indicating that food allergy was the cause of the mucous colitis in these cases. The method employed to detect the presence of sensitization consisted in the injection of foreign substance within the epidermis. The proof of relationship between the hypersensitiveness and clinical symptoms must depend, in the last analysis, not alone upon the positive dermal tests, but also upon the disappearance of symptoms when the offending material is withdrawn, or if that is impossible, when immunity can be established by methods of desensitization. In addition to the phenomenon of sensitization, mechanical factors must also be considered. When a mucous membrane is sensitized it is in an irritable state and coarse substances may cause symptoms from mere mechanical irritation. When the colitis is of a continuous nature uncommon articles of food need not be tested. In making the tests in the cases cited the author used seventy-five of the more common foods, and in all except one case found the patient sensitized to six or more articles of food.

**Occurrence of Paratyphoid-B Bacilli in Healthy Live Stock, Etc**—Dr M Friesleben refers to the original discovery by Uhlenhuth of the existence of an organism resembling the paratyphoid-B in healthy farm animals and also in dogs, rodents, etc. The next question to settle is whether these organisms are pathogenic to mankind. No attempt was made to inoculate volunteer human beings, the tests being limited to agglutination. These tests seem to have resulted chiefly in the negative throughout—that is, there was no reciprocal agglutination between strains known to be pathogenic in man and those cultivated from healthy animal dejections. An exception was found, however, in some sera obtained from grey mice and white rats, and here the two strains appeared identical both bacteriologically and serologically. Whether these small rodents can contribute to set up paratyphoid infection in man cannot yet be stated, but on general principles the author is in favor of a campaign of extermination against them.—*Deutsche medizinische Wochenschrift* September 16, 1927

**Clinical Studies of Bronchial Asthma**—Dr E Kylin of Jonköping, Sweden, has studied the physical basis of asthmatic subjects with the following conclusions. There is a pathological displacement in the metabolism which affects especially calcium, potassium, chlorine and water. There is a diminution in blood calcium with an excess of blood potassium, so that the potassium-calcium quotient is abnor-

mally high Immediately before an asthmatic crisis there is an increase of blood chlorine which is succeeded after the crisis by a diminution of the same The asthmatic also shows very high values of urinary calcium, and when calcium chloride is injected intravenously the percentage of calcium in the urine is abnormally high as compared with normal controls The adrenaline blood pressure reaction is vagotonic in the asthmatic subject which may be brought into relationship with the behavior of the potassium-calcium ratio The blood pressure of asthmatics may be too high or too low as a result of the insufficiency of the blood pressure-regulating apparatus The appearance of an asthmatic crisis is to be conceived of as complex Necessary is the asthmatic readiness or predisposition, which in turn is due to anomaly of metabolism, and in addition to this endogenous factor there must be an exogenous irritating factor corresponding to what was formerly termed a "miasm" Crises may also be of psychogenic origin—*Klinsche Wochenschrift*, September 10, 1927

**Dental Focal Infection** — Professor H. Schottmuller of the Hamburg-Eppendorf Hospital, writing both as clinician and bacteriologist, is firmly opposed to the American doctrine of dental focal infection as unproved and insusceptible of proof The idea did not at any rate originate among the Anglo-Americans, he says, for in 1885 von Kaczorowsky wrote of focal gingival infection, while in 1909 Passler anticipated the Englishman Hunter and the American Billings in advancing the modern theory The term sepsis, the author says, is poorly suited to characterize some of the innumerable symptoms, many functional, ascribed to this origin A distinction must of course, be made between active and silent infection, and the existence of the former is not disputed although its occurrence is relatively infrequent Endocarditis lenta is an affection which requires months and years to develop and it is not possible to associate infections of this type with the presence of the *Streptococcus viridans* in some focus of the moment The author's own laboratory experience does not uphold the claims of Rosenow In certain types of case a connection between a disease focus and another lesion is unmistakable, as in kidney infections from tonsillar lesions We cannot, however, deduce from this that infected teeth set up nephritis The author repudiates the entire theory of the dental or focal origin of muscular and articular rheumatism and his opinion is shared by such well known clinicians as Gudzent and Strauss (although Volhard has seen a connection be-

tween infected gums and nephritis, not a few of his nephritic patients having pyorrhea) Schottmuller says that not all Americans are partisans of the focal infection theory, and some of the dentists (he mentions only Thoma) are opposed to it There is a great body of negative evidence, beginning with Löffler, who never traced any systemic or remote infection to dead teeth, while in a material of thousands of children with caries there was none with infected joints Finally this sceptic says extirpation of foci frequently fails to cure—*Munchener medizinische Wochenschrift*, September 9, 1927

**The Non-Specific Treatment of Pneumonia** —Writing in the *Canadian Medical Association Journal*, October, 1927, xvii, 10, Fletcher McPhedran points to the fact that pneumonia is characterized by a severe toxemia with high fever and tachycardia He adduces evidence to show that cardiac failure never is the cause of death, but that the rapidly rising pulse with lowered blood pressure and the consequent dusky cyanosis so fatal in prognostic significance are due to vasomotor paralysis The effect of the toxemia is comparable to histamine shock What is needed, therefore, is an antidote to this histamine-like substance, which will increase blood pressure by general stimulation of all vessels Unfortunately such a substance is not known, but digitalis does favor constriction of various vascular areas, notably the vessels of the intestinal tract Hence its general effect is to increase the blood pressure This drug should be given early, as a routine, in all cases of pneumonia as soon as the diagnosis is made Within twenty-four hours the patient should receive at least four drachms of the British Pharmacopeia tincture, or the equivalent in dried leaves from a reliable source As evidence that an overdose of digitalis does no harm, two cases are cited in which the patients developed complete heart block and yet made uninterrupted recoveries In cases in which there is a return of fever after a normal or nearly normal period, or in which there is severe chest pain at any stage, the physician has cause to suspect empyema It is better then to aspirate, even a number of times, and find no fluid rather than to wait until one is sure Alcohol should be avoided except in patients addicted to its use, because it is the one drug that is notorious for doing what we fear may happen—lowering the blood pressure Distention is best treated by a diet containing an adequate protein ration The modern typhoid diet is ideal, soft boiled eggs, scraped beef, jellies, junkets, or custards may be given at two-hour intervals

# LEGAL

By LLOYD PAUL STRYKER, Esq  
Counsel, Medical Society of the State of New York

## THE MEDICO-LEGAL ASPECTS OF DRUNKENNESS

Despite the Eighteenth Amendment and the Volstead Law, drunkenness is still with us, its presence, its manifestations and its effect are subjects repeatedly considered both by the medical profession and by the courts

Both in the civil and in the criminal tribunals, the question of intent, motive and other operations of the mind are constantly the subject of investigation. Thus, for example, the New York Penal Law provides that "no act committed by a person while in a state of voluntary intoxication, shall be deemed less criminal by reason of his having been in such condition. But whenever the actual existence of any particular purpose, motive, or intent is a necessary element to constitute a particular species or degree of crime, the jury may take into consideration the fact that the accused was intoxicated at the time, in determining the purpose, motive, or intent with which he committed the act." (Penal Law, Sec 1220)

In practically all of the more serious crimes, i e, those known as *mala in se*, the question of intent is vitally involved. Thus, for example, murder in the first degree is defined as the killing of a human being "from a *deliberate and premeditated design* to effect the death of the person killed, or of another"

A person is guilty of larceny who with "intent to deprive or defraud the true owner of his property, takes from the possession of the true owner any money, personal property, etc"

And so on through the long category of the statutes defining criminal offenses, intent is found as a necessary ingredient of the crime

Even in the minor crimes, i e, those designated as *malum prohibitum*, the question of intoxication frequently is involved. Thus, our Highway Law declares that "whoever operates a motor vehicle while in an intoxicated condition shall be guilty of a misdemeanor"

In civil transactions, too, the mental condition of the parties is a vital consideration. Thus, in determining whether or not a legal contract has been made, one of the essential inquiries is was there a meeting of the minds? There could be no legal meeting of the minds unless the minds were in a condition to meet. This meeting involves or presupposes a voluntary and conscious act. Thus, if one party to an agreement secures the other's signature by means of first reducing him to a state of intoxication,

there could not be in any legal sense a meeting of the minds

In cases involving testamentary capacity, also the question of drunkenness is frequently involved. Thus, for example, it has been held that drunkenness in such a degree as to render a testator unconscious of what he is about, or less capable of resisting the influence of others, voids a will

This discussion of the occasions when intoxication becomes the vital question in the courts might be expanded indefinitely. Enough has been said to prove its importance

This inquiry naturally leads to the question What is drunkenness? The Century Dictionary defines drunkenness as "the state of being drunk or overpowered by intoxicants". A less satisfactory definition is given in Bouvier's Law Dictionary as follows "The condition of a man whose mind is affected by the immediate use of intoxicating drinks". This definition is unsatisfactory because of the indefinite meaning of the word "affected". A person's mind may be affected by the use of tobacco or tea or coffee. What is really meant by the word "drunkenness" is better set forth in the Corpus Juris definition, which defines it as any one of six conditions, as follows

"Under the influence of intoxicating liquor to such an extent as to have lost the normal control of one's bodily and mental faculties, and, commonly, to evince a disposition to violence, quarrelsomeness, and bestiality,"

"Under the influence of intoxicating liquors to the extent that they affect one's acts or conduct, so that persons coming in contact with him could readily see and know that the intoxicating liquors were affecting him in that respect,"

"Under the influence of an intoxicant, especially an alcoholic liquor, so that the use of the faculties is materially impaired,"

"So far under the influence of intoxicating liquor that one's passions are visibly excited or his judgment impaired by the liquor,"

"The condition of a man whose mind is affected by the immediate use of intoxicating drinks,"

"The result of excessive drinking of intoxicants," (19 C J 791)

When some years ago, the writer and his former partner, Mr Whiteside, were engaged with the Hon Elihu Root and the Hon Wil-

liam D Guthrie in the case of Hoffman Brewing Co v McElligott, which involved the validity of war-time prohibition, we evolved a definition of intoxication from a survey of all of the cases in this country. The definition which we then devised was accepted by the courts and was stated in these words:

"Drunkenness or intoxication is a materially abnormal mental or physical condition, manifesting itself in the loss of the ordinary control of the mental faculties or bodily functions to an appreciable or material extent."

Thus, to constitute drunkenness in the legal sense, the drinking of intoxicating liquors must result in a mental or physical condition which must be "materially abnormal." This condition must be such as to manifest itself "in the loss of the ordinary control of the mental faculties or bodily functions," and this loss of control must be to "an appreciable or material extent."

It is therefore, not sufficient that the mind or body must be "affected" by intoxicating liquors, the effect must result in a material or appreciable loss of mental or bodily functions.

Whether or not then, a person is drunk in the legal sense, involves a complicated question. In reality it is a scientific question, comprising the pathology of mental and bodily functions, an understanding of their normal condition, and an ability to differentiate between the normal and the abnormal. Despite the complicated character of this question, it has been uniformly held in this state that whether or not a person is drunk is a question upon which the testimony of a lay witness is competent.

In a very early case in the Court of Appeals, it was held that a lay witness might properly be asked what, in his judgment, was the condition of the prisoner as to sobriety. This question, said the court, "did not become incompetent by adding the words, 'in your judgment,' while the judgment was restricted to what the witness saw. A child six years old may answer whether a man (whom it has seen) was drunk or sober, it does not require science or opinion to answer the question, but observation merely, but the child could not, probably, describe the conduct of the man, so that, from its description, others could decide the question. Whether the person is drunk or sober, or how far he was affected by intoxication, is better determined by the direct answer of those who have seen him than by their description of his conduct." (People v Eastwood, 14 N Y 566)

This really presents an exception to the general requirement that opinions can only be given by experts. This exception was defined by the Court of Appeals in a more recent case as follows:

"Opinions are also allowed in some cases

where, from the nature of the matter under investigation, the facts cannot be adequately placed before the jury so as to impress their minds as they impress the mind of a competent, skilled observer, and where the facts cannot be stated or described in such language as will enable persons not eyewitnesses to form an accurate judgment in regard to them, and no better evidence than such opinions is attainable." "Farmers may be permitted to give their opinions of the value of farms, and farm stock, and product, witnesses may give their opinions on questions of identity, or whether a person is *under the influence of liquor*, and as to many other matters'" (Felska v N Y Central & Hudson River R R Co, 152 N Y 339, 344)

But although lay opinion on this question is competent in the courts, this does not by any means imply that the opinion of an expert is incompetent. While a lay person from common knowledge may be allowed to give an opinion as to whether or not a person is drunk, far more valuable and convincing proof could be adduced through the testimony of a physician who had examined the person, his mental and bodily functions, and from his expert knowledge could thus draw a comparison between the normal and the abnormal, and upon the basis of this knowledge and examination, render an opinion that the mental and bodily functions of the person in question were abnormal to a material or appreciable extent, and that this abnormality had been caused by drinking liquor.

Experience shows that while lay persons are willing to testify as to the physical condition of a person and express an opinion as to the drunkenness of such person, physicians are hesitant and reluctant to give an expert opinion that a person was drunk, even after he has examined the person and observed the actions and conduct of such person.

We believe that the medical literature upon this subject is meager and scattered and not readily accessible to physicians. Thus, there should be, as we believe there are not, well accepted tests for the purpose of detecting the presence of alcohol in the body, as well as those for diagnosing abnormal mental states associated with alcohol. This much, we are informed, is generally accepted—that alcohol is absorbed into the blood and circulates as such, and is found in measurable quantities in the brain, liver, and other organs for several hours after it is swallowed, and its effects on the nervous system and mentality are characteristic and progressive in proportion to the amount of alcohol circulating in the body. What still remains to be done is the development of quantitative tests, both chemical and psychological, that will exactly express the correla-

tions between the alcoholic content of the blood and the degree of the resulting mental abnormality

Since scientific research has disclosed the conditions in ether anaesthesia and in carbon monoxide poisoning, it should succeed equally well in alcoholic poisoning. The tests at first may be difficult and intricate, and require expert investigators working with special apparatus, but the history of all such tests is not

only that they are progressively simplified, but also that physicians learn their application and use them as soon as they are practical and reliable. One of the important contributions which medicine still has to make to the cause of justice, is a scientific test whereby a physician can diagnose the amount of alcohol in the body and the resulting mental abnormality of the patient

---

### FRACTURE OF ANKLE

In this action the plaintiff on September 8th sustained an injury to her left foot, and called the defendant as a physician to treat her. It is charged that he negligently and carelessly, and through want of skill failed to set and treat the bones of the arch of plaintiff's foot and of the ankle, that the damage has been occasioned thereby consisting of severe inflammation of the injured part, ankylosis and improper formation of callus resulting in a permanent injury, and the plaintiff seeks in this action to recover damages for such injury.

On September 8th, when the defendant was called to attend the plaintiff, she gave him a history of having stepped from a trolley car on a railroad track and having turned her ankle. She complained of great pain and difficulty in walking. Upon examination, he found a badly swollen ankle and ecchymosis of both sides of the ankle. The patient was apparently suffering great pain, and the ankle was very tender. The patient, however, was oversensitive, and it was with great difficulty that any treatment could be rendered to her. Because of pain, swelling, and ecchymosis presenting symptoms of fracture, the defendant applied a plaster cast to the plaintiff's foot on September 11th.

The defendant at various times advised the plaintiff to have an X-ray taken, but this she refused to do, stating that it was not necessary. Finally, after the defendant had advised the plaintiff that he would not proceed further with the treatment unless an X-ray was taken, she consented. The X-ray showed that there was a fracture of the lower end of the tibia with the fragments in good apposition.

When the patient was seen on September 13th, she complained of pain and discomfort, so that the defendant split the cast, examined the foot and ankle, but observed nothing unusual to cause the great discomfort the patient complained of. On September 26th, the cast was removed, the injured parts examined, and

a light cast applied to assist locomotion. The defendant advised active and passive motion and massage for the injured parts. On October 9th, he arranged with a masseur to call upon the plaintiff and to give her the necessary manipulations.

Because of the disagreeableness and unreasonableness of the patient, the masseur requested that he be relieved from further attending the plaintiff, and he stated that she had refused to allow any treatment that would be of value. Manipulations were given by the masseur on October 9th, 10th, 11th and 12th, and because of the patient's conduct, the masseur discontinued attending her.

On October 13th, when the defendant physician called upon the plaintiff, she refused to allow him to examine or manipulate the foot. She also stated that someone at her place of employment doubted that her foot had been properly cared for, and that she was going to some other physician. When the defendant called upon her on October 16th, she advised him that the treatment of her foot was in the hands of another doctor. During the course of the defendant's treatment, the patient's foot was at no time deformed, there was no displacement of the bones that could in any way interfere with the function of the ankle, except the swelling that sometimes follows fractures of this nature. This patient insisted upon holding the foot extended, walked on her toes, and refused to exercise it, thereby tending toward permanent extension of the foot. Because of the patient's attitude and conduct, the defendant was unable to render any effective service, and was discharged from treatment of the plaintiff long before any permanently beneficial results were expected.

When this case came on for trial, the plaintiff submitted her evidence in support of her contentions, at the close of which the Court directed a verdict in favor of the defendant dismissing the complaint.

liam D Guthrie in the case of Hoffman Brewing Co v McElligott, which involved the validity of war-time prohibition, we evolved a definition of intoxication from a survey of all of the cases in this country. The definition which we then devised was accepted by the courts and was stated in these words:

"Drunkenness or intoxication is a materially abnormal mental or physical condition, manifesting itself in the loss of the ordinary control of the mental faculties or bodily functions to an appreciable or material extent."

Thus, to constitute drunkenness in the legal sense, the drinking of intoxicating liquors must result in a mental or physical condition which must be "materially abnormal." This condition must be such as to manifest itself "in the loss of the ordinary control of the mental faculties or bodily functions," and this loss of control must be to "an appreciable or material extent."

It is therefore, not sufficient that the mind or body must be "affected" by intoxicating liquors, the effect must result in a material or appreciable loss of mental or bodily functions.

Whether or not then, a person is drunk in the legal sense, involves a complicated question. In reality it is a scientific question, comprising the pathology of mental and bodily functions, an understanding of their normal condition, and an ability to differentiate between the normal and the abnormal. Despite the complicated character of this question, it has been uniformly held in this state that whether or not a person is drunk is a question upon which the testimony of a lay witness is competent.

In a very early case in the Court of Appeals, it was held that a lay witness might properly be asked what, in his judgment, was the condition of the prisoner as to sobriety. This question, said the court, "did not become incompetent by adding the words, 'in your judgment,' while the judgment was restricted to what the witness saw. A child six years old may answer whether a man (whom it has seen) was drunk or sober, it does not require science or opinion to answer the question, but observation merely, but the child could not, probably, describe the conduct of the man, so that, from its description, others could decide the question. Whether the person is drunk or sober, or how far he was affected by intoxication, is better determined by the direct answer of those who have seen him than by their description of his conduct." (People v Eastwood, 14 N Y 566.)

This really presents an exception to the general requirement that opinions can only be given by experts. This exception was defined by the Court of Appeals in a more recent case as follows:

"Opinions are also allowed in some cases

where, from the nature of the matter under investigation, the facts cannot be adequately placed before the jury so as to impress their minds as they impress the mind of a competent, skilled observer, and where the facts cannot be stated or described in such language as will enable persons not eyewitnesses to form an accurate judgment in regard to them, and no better evidence than such opinions is attainable." "Farmers may be permitted to give their opinions of the value of farms, and farm stock, and product, witnesses may give their opinions on questions of identity, or whether a person is *under the influence of liquor*, and as to many other matters." (Felska v N Y Central & Hudson River R R Co, 152 N Y 339, 344.)

But although lay opinion on this question is competent in the courts, this does not by any means imply that the opinion of an expert is incompetent. While a lay person from common knowledge may be allowed to give an opinion as to whether or not a person is drunk, far more valuable and convincing proof could be adduced through the testimony of a physician who had examined the person, his mental and bodily functions, and from his expert knowledge could thus draw a comparison between the normal and the abnormal, and upon the basis of this knowledge and examination, render an opinion that the mental and bodily functions of the person in question were abnormal to a material or appreciable extent, and that this abnormality had been caused by drinking liquor.

Experience shows that while lay persons are willing to testify as to the physical condition of a person and express an opinion as to the drunkenness of such person, physicians are hesitant and reluctant to give an expert opinion that a person was drunk, even after he has examined the person and observed the actions and conduct of such person.

We believe that the medical literature upon this subject is meager and scattered and not readily accessible to physicians. Thus, there should be, as we believe there are not, well accepted tests for the purpose of detecting the presence of alcohol in the body, as well as those for diagnosing abnormal mental states associated with alcohol. This much, we are informed, is generally accepted—that alcohol is absorbed into the blood and circulates as such, and is found in measurable quantities in the brain, liver, and other organs for several hours after it is swallowed, and its effects on the nervous system and mentality are characteristic and progressive in proportion to the amount of alcohol circulating in the body. What still remains to be done is the development of quantitative tests, both chemical and psychological, that will exactly express the correla-

"The physicians of Cattaraugus County had not rested with destructive criticism, they had expressed their opinion by the constructive suggestion that Cattaraugus County should have a health department to be conducted along the modest plan that had been outlined by Dr Paul B Brooks, Deputy State Commissioner of Health, as published on page 985 of the December first, 1926, issue of this JOURNAL. The County Society had also appointed a committee to devise a definite plan for a county health department and should present it to the Board of Supervisors of Cattaraugus County at its meeting on November fifteenth (See page 1333)

"The essential part of the plan is that the county health department shall be conducted and managed by the citizens of Cattaraugus County, and that the County Medical Society, representing the physicians of the County, and the local health officers, shall be the recognized advisors, and so far as is practical, the operating agency, of the department

"One feature of the plan is that it provides for the acceptance of gifts and endowments to be managed and dispensed by an advisory committee composed of citizens of Cattaraugus County

"Provision is also made for the recognition of

the State Department of Health in conducting all public health work in the County"

In closing, Dr Garen said

"You physicians of Long Island must recognize the fact that your geographic situation makes you peculiarly well adapted for leadership in all phases of public health work. The influence of Kings County is felt through the whole Island, and you are all united through your Island-wide medical societies and your *Long Island Medical Journal*. Your County Societies have been engaged in public health work for at least ten or fifteen years, and when the lay organizations entered the field of public health, they found that your societies were already occupying the field, and that they had to assist the doctors rather than dominate them. Your program tonight demonstrates your leadership

"In contrast to you, the Cattaraugus County Medical Society has hitherto permitted an outside agency composed of laymen to dominate the practice of public health, and now it is undertaking to do in fifteen weeks what it has taken you fifteen years to do. I assure you that we physicians of Cattaraugus County have noted your methods of public health work, and have taken them as our models"

---

## POST GRADUATE INSTRUCTION

The Committee on Public Health and Medical Education announces that courses have been arranged for three counties in addition to those already noted in the JOURNAL.

Four lectures on Heart Diseases have been given in Herkimer in the North Washington Street School Building on Thursdays at 3 30 o'clock, as follows

October 20th Bacterial Endocarditis—I Harris Levy, Professor of Medicine, Syracuse University

October 27th Arythmia—Recognition and Treatment, Dr Clayton W Greene, Associate Professor of Medicine, University of Buffalo

November 3rd Valvular Lesions and Myocarditis—Dr John H Wyckoff, Associate Professor of Medicine, University of New York

November 10th Hypertension, including blood chemistry, blood pressure and treatment, Dr Wm McCann, Professor of Medicine, University of Rochester

A series of six lectures have been given at Lyons, on Friday afternoons at 3 30 o'clock, as follows

October 14th Preventive Medicine—Dr O W H Mitchell, Professor of Bacteriology, Hygiene and Sanitation, Syracuse University

October 21st Gastro-Enterology, Dr A. H

Aaron, Professor of Medicine, University of Buffalo

October 28th Physical Diagnosis (Lungs and Heart), Dr E C Reiffenstein, Professor of Clinical Medicine, Syracuse University

November 4th Obstetrics, Dr Henry Schoeneck, Professor of Obstetrics, Syracuse University

November 11th Sinuses and the Ear, Dr E J O'Connor, Assistant Professor Otolaryngology, Syracuse University

November 18th Eye, Dr David Gillette, Professor Ophthalmology, Syracuse University

The announcement of these two courses have been in the form of News Sheets sent to the newspapers of the two counties, and explaining the objects of the lectures. They are admirably designed for the instruction of the public regarding the measures taken by physicians to keep their knowledge up to date

Clinton County has announced a course of lectures by Dr Harris A Houghton, similar to those given by Dr Houghton in Amsterdam, Montgomery County, in 1926, and published in the August fifteenth, 1926, issue of this JOURNAL.

THOMAS P FARMER, *Chairman*

# NEWS NOTES

## SECOND DISTRICT BRANCH

The Second District Branch of the Medical Society of the State of New York, composed of the four counties of Long Island, held its annual meeting on the evening of Wednesday, November 9, in the Chamber of Commerce Building, corner of Livingston and Court Streets, Brooklyn. The President of the Branch, Dr. Guy H. Turrell, presided, and over one hundred members were in attendance.

The details of the meeting had been arranged by a committee of which Dr. Thurston S. Welton, President of the Medical Society of the County of Kings, was chairman. The Committee sent out three programs and reminders to every member of the District Branch. The first one was a preliminary description written in conversational style, and was printed on page 1213 of the November first issue of the JOURNAL. The second announcement was the official program which was distinctive from the usual form of notices of District Branch meetings. The third notice was a postal card reminder.

The program was carried out almost exactly as it was announced. The members sat down to a social supper promptly at seven o'clock. The addresses were begun at 8:45 instead of 8:30 as announced, simply because the members declined to tear themselves apart from conversational groups which, like agglutination tests, had shown that the members were susceptible to the ideals of the Medical Societies.

The program was entirely on organized medicine. First were reports of the activities of each of the four County Medical Societies on Long Island, and were given as follows:

"Suffolk County," Dr. W. H. Ross, Brentwood  
 "Nassau County," Dr. Louis A. Van Kleeck, Manhasset

"Queens County," Dr. Francis G. Riley, Jamaica

"Kings County," Dr. Thurston S. Welton, Brooklyn

These reports were carefully prepared, and were short and concise. They are printed on page 1309 of the Scientific department of this JOURNAL.

Dr. James E. Sadlier, President of the Medical Society of the State of New York, then addressed the meeting on "The Relation of the Medical Society of the State of New York to the Physicians of Long Island." His address was a fitting commentary on the aspirations and accomplishments of the four County Medical Societies on Long Island. It is printed on page 1312 of this JOURNAL.

President Turrell, in introducing the next speaker, said that the program committee planned to have a speaker from an up-State society that was especially active in public health, and had chosen Cattaraugus County in the opposite end of the State from Long Island, and had invited the President of the County Medical Society, Dr. Joseph P. Garen, of Olean, to describe the relation of the physicians to the Cattaraugus County Department of Health, which is the first and only county department of health in New York State.

Dr. Garen held the close attention of his audience for an hour with his vivid descriptions. He said:

"The County Medical Societies of Long Island took up the practice of public health and civic medicine over ten years ago, and have carried on all forms of health work on their own initiative and with the assistance of lay organizations, all of which had accepted the leadership of the physicians. In contrast with this method a strong lay organization, the Milbank Fund, had come into Cattaraugus County and spent over \$100,000 annually in conducting a county health department that should demonstrate how the impersonal methods of the department of health of a large city could be applied with efficiency to a rural county. The offer was made in 1922, and the general plan was accepted by the Cattaraugus County Medical Society in the expectation that the physicians of the County would be consulted in regard to all the plans for the work of the department, and that their advice should be given careful consideration.

"After the demonstration had continued for four years, the County Medical Society conducted a questionnaire which was answered by practically all the physicians of the County, regardless of membership in the County Medical Society. The result of the questionnaire was considered by the County Medical Society on August 4, 1927, and was printed on page 1041 of the September fifteenth issue of the NEW YORK STATE JOURNAL OF MEDICINE. The action of the Society was to the effect that a large majority of the physicians of Cattaraugus County felt that a large part of the demonstration had not been along practical lines, and that it should be discontinued. One ground for the unfavorable attitude of the physicians was that the managers and officials of the demonstration had given little attention to the physicians and local health officers of the County, while the physicians were firm in their belief that any program of county health work must have the active support of the physicians if it is to be successful.

Hampshire Medical Society, described the New England conference which is composed of the elected officers of the medical societies of each of the six New England States, together with five members from each state elected by its House of Delegates. These members will meet twice a year to consider problems common to all the states. One of the greatest benefits will be the publication of a single Journal, probably to be called the New England Medical Journal, which should be the organ of the six state societies. Only three New England state societies, Maine, Massachusetts and Rhode Island, now publish their own Journals. These will be merged into one as soon as the Massachusetts organ, the *Boston Medical Journal*, can legally enter the agreement, it being under contract to continue its corporate name for a period of one hundred years, which expires on December 31 of next year.

The subject of the annual meeting of the State Society was presented in three parts:

1 The Program, by Dr. Holman Taylor, Secretary of the State Medical Association of Texas.

2 The Exhibits, by Dr. F. B. Stephenson, Secretary Colorado State Medical Society.

3 Observations of Several State Meetings, by Dr. Morris Fishbein, Editor of the *Journal of the American Medical Association*.

Dr. Taylor presented arguments in favor of a permanent committee on program in distinction from a committee appointed from year to year. He said that the Texas Society always had a general session every day of the annual meeting, in which subjects on economics and education and other society topics could be discussed. He said that the general session afforded the only opportunity for the free discussion of those topics which are of general interest to the entire body of physicians of the state.

Dr. Stephenson said there were two kinds of exhibits—the scientific and the commercial—both being shown by the annual meeting of the A. M. A. Colorado had tried the experiment of inviting each county society to put on a scientific exhibit on a particular subject, and all of the larger societies had responded. One arranged an exhibit on tularemia, and another illustrated the history of the discovery of the circulation of the blood. The plan not only produced an exhibit that was highly creditable, but it stimulated study by the local societies.

The management of commercial exhibits had sometimes been left to local committees of arrangements, and they were under the temptation to accept unethical advertisers in order to make the exhibit financially successful. It was better that the State Society should manage the commercial exhibit on an ethical basis.

One speaker said that his state limited the exhibitors to those who advertised in the *State Journal*.

The location of the exhibits had much to do with their success. It was best to put them where members had to pass on the way to the registration desk or meeting room.

Provision for publicity has a place on every program. Some societies require the speakers to supply abstracts of their addresses to be given to reporters of the daily newspapers.

Giving news of the proceedings to the daily press was an effective means of educating the people regarding the aims and accomplishments of the physicians.

Dr. McCormack said that the Woman's Auxiliary of Kentucky was collecting material for a historical exhibit to be given at the next State meeting.

Dr. Morris Fishbein described some of his observations at the meetings of twelve state societies which he had attended during the past two years.

One society which ran its sessions in competition with a golf meeting had only a handful of members to greet a nationally known guest.

Another society put on a number of different sub-meetings at the same time and none were much of a success.

Dr. Fishbein described the operation of the political machines of two societies, resulting in a stifling of all discussion and freedom of choice, and in dissatisfaction among the members.

Dr. Olin West said that as the State Medical Societies prospered, they gave necessary consideration to the employment of a fulltime secretary. He introduced Dr. Percy T. Philips, President of the California Medical Association, who described the form of incorporation which the state society was adopting in order to accept gifts of property, which would enable the society to employ fulltime officials.

The subject of the Free Clinic was introduced by Dr. Henry O. Reik, Editor of the *Journal of the Medical Society of New Jersey*. Dr. Reik reviewed the three principal forms of free clinics.

1 The hospital and dispensary, 2, the diagnostic clinic, and 3, the prenatal and children's clinics. He emphasized their good points and pointed out the proper lines for their management.

The discussion of Dr. Reik's paper was along the lines that are familiar to the members of the Medical Society of the State of New York, where graduate education of physicians, and children's diagnostic clinics are established facts.

## CONFERENCE OF STATE SECRETARIES AND EDITORS

The annual conference of the Secretaries of State Medical Societies and Editors of State Journals was held on November 18th and 19th in Chicago, Illinois, under the auspices of the American Medical Association. This meeting accords those who are most intimately concerned with the field work of the State Societies the opportunity to meet their brethren from other States and to discuss their mutual problems both officially and informally. The attendance from the several states was as follows:

Secretaries	39
Editors	11
Boards of Trustees	9
Other Officers	14
Total	<hr/> 73

The general officials of the A M A and the heads of its bureaus were also present, and showed the visitors every possible courtesy. All those attending the conference were guests of the A M A at a noon luncheon in the Hotel Virginia.

The meeting was opened at 10 20 o'clock on Friday, November 18, by Dr Olin West, general manager of the American Medical Association, who asked the doctors to choose a presiding officer, and Dr A T McCormack of Louisville, Secretary of the Kentucky State Medical Association was elected. Dr McCormack, who is the son of one of the leaders who planned the modern organization of the A M A, presided with a rare combination of humor and wisdom.

The first speaker was Dr Jabez N Jackson of Kansas City, President of the American Medical Association, who spoke on the recognition of the physician by the public, and said:

"While medical organizations have been reminding doctors of their duty to serve the people in all health matters, the time has come to remind the people of their duty to recognize the value of the services of the doctors. The medical education of the people generally is one of the great ideals which the A M A is upholding."

Dr W C Woodward, Executive Secretary of the Bureau of Legal Medicine and Legislation of the A M A, addressed the meeting on the Basic Science Law. He explained that this was the law intended to apply to all who aspired to study any legally recognized system of the healing art whether in regular medicine or any of the cults, including chiropractic. The basic sciences were anatomy, physiology, chemistry, bacteriology and pathology, and to this list two states added diagnosis.

The five states that had enacted basic science laws were Connecticut, Minnesota, Nebraska, Washington, and Wisconsin. The results of the administration of the laws had been generally

satisfactory. It was not intended that the law should be promoted in those states which already have an excellent practice of medicine law. New York State, for example, requires every one who practices the healing art to pass an examination in not only the basic sciences, but also in medical branches.

Dr Woodward said "A law is a prescription given by the legislature to improve the welfare of the people, or to alleviate or cure the ills of the community. The basis for giving a prescription is knowledge of the condition of the patient. If the legislatures do not correctly diagnose the medical situation, it is not ready to draft a proper law. Moreover, after a law has been prescribed, it is of no effect unless it is properly administered."

There was considerable discussion of the laws relating to medical practice. Dr O S Wightman, Editor-in-Chief of the NEW YORK STATE JOURNAL OF MEDICINE, said that he was also Chairman of the Grievance Committee established by the Medical Practice Act of 1925, and that he had found that for every illegal practitioner convicted ten left the State. Every illegal practitioner had taken in his sign calling himself a doctor.

Dr D S Dougherty, Secretary of the Medical Society of the State of New York, said that physicians should not rest when they have secured a medical practice law. They must give their active aid in support of the law. If doctors cease their efforts, so will the representatives of the people, for the doctors set the people's standard in medicine and hygiene.

Dr Dougherty also spoke of the need of a fund to enforce the law. New York derives the fund from an annual license fee of two dollars imposed on the doctors for annual registration. Doctors had opposed the fee at first on the ground that they were already giving valuable services to the people free, but now that the system is in operation they recognize the justice of the license fee that gives them an exclusive right to engage in a remunerative line of work.

The subject of interstate conferences was introduced by Dr J B Morrison, Secretary of the Medical Society of New Jersey, who described the Tri-State Conferences held three times a year by the officers of the Medical Societies of New Jersey, Pennsylvania and New York. (See this JOURNAL, November 1, 1927, page 1214.)

Dr Earl Whedon, Secretary of the Wyoming State Medical Society, said that his society is planning to hold a joint meeting with the societies of Montana and Idaho next summer in the Yellowstone Park.

Dr D E Sullivan, Secretary of the New

Hampshire Medical Society, described the New England conference which is composed of the elected officers of the medical societies of each of the six New England States, together with five members from each state elected by its House of Delegates. These members will meet twice a year to consider problems common to all the states. One of the greatest benefits will be the publication of a single Journal, probably to be called the New England Medical Journal, which should be the organ of the six state societies. Only three New England state societies, Maine, Massachusetts and Rhode Island, now publish their own Journals. These will be merged into one as soon as the Massachusetts organ, the *Boston Medical Journal*, can legally enter the agreement, it being under contract to continue its corporate name for a period of one hundred years, which expires on December 31 of next year.

The subject of the annual meeting of the State Society was presented in three parts:

1 The Program, by Dr. Holman Taylor, Secretary of the State Medical Association of Texas.

2 The Exhibits, by Dr. F. B. Stephenson, Secretary Colorado State Medical Society.

3 Observations of Several State Meetings, by Dr. Morris Fishbein, Editor of the Journal of the American Medical Association.

Dr. Taylor presented arguments in favor of a permanent committee on program in distinction from a committee appointed from year to year. He said that the Texas Society always had a general session every day of the annual meeting, in which subjects on economics and education and other society topics could be discussed. He said that the general session afforded the only opportunity for the free discussion of those topics which are of general interest to the entire body of physicians of the state.

Dr. Stephenson said there were two kinds of exhibits—the scientific and the commercial—both being shown by the annual meeting of the A. M. A. Colorado had tried the experiment of inviting each county society to put on a scientific exhibit on a particular subject, and all of the larger societies had responded. One arranged an exhibit on tularemia, and another illustrated the history of the discovery of the circulation of the blood. The plan not only produced an exhibit that was highly creditable, but it stimulated study by the local societies.

The management of commercial exhibits had sometimes been left to local committees of arrangements, and they were under the temptation to accept unethical advertisers in order to make the exhibit financially successful. It was better that the State Society should manage the commercial exhibit on an ethical basis.

One speaker said that his state limited the exhibitors to those who advertised in the State Journal.

The location of the exhibits had much to do with their success. It was best to put them where members had to pass on the way to the registration desk or meeting room.

Provision for publicity has a place on every program. Some societies require the speakers to supply abstracts of their addresses to be given to reporters of the daily newspapers.

Giving news of the proceedings to the daily press was an effective means of educating the people regarding the aims and accomplishments of the physicians.

Dr. McCormack said that the Woman's Auxiliary of Kentucky was collecting material for a historical exhibit to be given at the next State meeting.

Dr. Morris Fishbein described some of his observations at the meetings of twelve state societies which he had attended during the past two years.

One society which ran its sessions in competition with a golf meeting had only a handful of members to greet a nationally known guest.

Another society put on a number of different sub-meetings at the same time and none were much of a success.

Dr. Fishbein described the operation of the political machines of two societies, resulting in a stifling of all discussion and freedom of choice, and in dissatisfaction among the members.

Dr. Olin West said that as the State Medical Societies prospered, they gave necessary consideration to the employment of a fulltime secretary. He introduced Dr. Percy T. Philips, President of the California Medical Association, who described the form of incorporation which the state society was adopting in order to accept gifts of property, which would enable the society to employ fulltime officials.

The subject of the Free Clinic was introduced by Dr. Henry O. Reik, Editor of the *Journal of the Medical Society of New Jersey*. Dr. Reik reviewed the three principal forms of free clinics.

1 The hospital and dispensary, 2, the diagnostic clinic, and 3, the prenatal and children's clinics. He emphasized their good points and pointed out the proper lines for their management.

The discussion of Dr. Reik's paper was along the lines that are familiar to the members of the Medical Society of the State of New York, where graduate education of physicians, and children's diagnostic clinics are established facts.

Dr J H Bunce, Secretary of the Georgia Medical Association, told of the difficulty of carrying medical service to the people in inaccessible parts of the State, and said that three men had qualified as midwives in a mountainous district and were giving excellent service where physicians and women midwives could not go. He also said that the railroads were giving special rates or even free transportation so that children may go to hospitals for needed operations.

Dr T E Powers described the working of the Iowa law by which counties were requested to pay the expenses of transportation and operation for crippled children. He said that it had been extended to other conditions and had been abused by adults accompanying

children and remaining with them for considerable periods.

One speaker objected to a statement that doctors must assist lay organizations in carrying out their health programs. The speaker said that it is the lay organizations that should do the assisting, while the doctors dominate the lay organizations and dictate their policies in free clinics and all their other activities.

The conference elicited a wealth of information and ideas which are here recorded from the point of view of their interest to the physicians of New York State. Of special importance are the records which other states show in activities which are contemplated or undertaken under the auspices of the Medical Society of the State of New York.

---

### KINGS COUNTY MEDICAL SOCIETY

The November Bulletin of the Medical Society of the County of Kings contains an item which is of interest to physicians throughout the State of New York. The article is an emphatic denial of the story printed in the *Brooklyn Daily Eagle* on October 27, under the caption, "Medical Society Here Plans For Big Academy. Seeks Divorce from State Body, and \$1,000,000 to Erect Building." The Bulletin says:

"The medical body seeking divorce in order to become independent, is one of those figments of the imagination that would have been corrected, if the *Eagle* had followed the proper and agreed upon form of procedure. The Press Reference Committee was not consulted about the article until after the paper had gone to press.

"A correction was agreed upon by the *Eagle* and the Chairman of the Press Reference Committee. It appeared on October 28th."

The Press Reference Committee referred to was formed as the result of a regular meeting of the Society held on March 18, 1924, at which the editors of the leading Brooklyn newspapers were the principal speakers. This meeting was reported in full in the October, 1924, issue of the *Long Island Medical Journal*. The Committee has done its part promptly and well, and it is to the credit of the *Brooklyn Daily Eagle* that in this case it at once printed the correction when the Committee called its attention to its error.

The corrected article quotes Dr Frank D Jennings, Chairman of the Board of Trustees of the Kings County Medical Society, regarding the plan to change the name of the Society and gen-

erally to broaden its scope of activities, as follows:

"It has no relation to the State Medical Society or to any differences that may have existed in the past.

"The Kings County Society has actually for years been carrying on the functions of an academy of medicine. It maintains a large public medical library, it has an active public health committee, it cooperates with the Brooklyn Chamber of Commerce in the Brooklyn Health Council, it offers in conjunction with the Long Island College Hospital courses in graduate education, in addition to giving in its own auditorium weekly lectures by the most eminent teachers to be found.

"These are properly functions of an academy of medicine, and it is recognition of this fact that has prompted the present movement to amend our corporate title."

The Bulletin continues:

"It is regrettable, in the haste of publication, that such a serious distortion of the facts occurred. The recommendation of the Council to the Society, not as yet acted upon, is that the corporate title be amended to include 'and the Academy of Medicine of Brooklyn'. That is merely recognition and affirmation of the fact that we are now an 'Academy of Medicine' by virtue of our various activities, a large library, an active Public Health Committee, graduate medical teaching, etc. It had no relation to the State Society. It is no novelty, having been done in Toledo and elsewhere."

## SUFFOLK COUNTY

The Annual Meeting of the Suffolk County Medical Society was held on Thursday, October 27, 1927, with the President, Dr Frank Overton, in the chair and the Secretary, Dr E P Kolb, recording

The weather was mild and balmy, and the veranda of the Club House of the Riverhead Golf Club made an ideal meeting place. The meeting was opened at 11 30 o'clock, and some business was transacted during the luncheon hour, which began at 1 20 o'clock. After the luncheon, a scientific session was held and at 3 15 o'clock the meeting adjourned. The attendance was thirty-two members, three visiting physicians, and eight public health nurses and social workers.

The greater part of the program consisted of reports on the activities of the Society, especially in the practice of public health and civic medicine. The Medical Society represents the doctors of Suffolk County, and the program of the meeting was designed to show the various ways in which the medical profession discharges its civic duties to the community. The family practice of medicine according to the highest standards, is a civic duty in whose promotion the Suffolk County Medical Society has been engaged for one hundred and twenty-one years. But in addition to their private practice, the physicians of Suffolk County take a leading interest in every phase of health work whose accomplishment requires community effort, such as hospital management, the work of official departments of health, the activities of the County Tuberculosis and Public Health Association, the work of the County Board of Child Welfare, and the education of the people in public health. The program included reports not only from the physicians, who were the leaders in the community activities, but also from the lay executives who were carrying on the non-medical details of health work. Every report had been prepared in writing for the sake of both brevity and clearness, and all were given within the allotted time with snap and animation. This part of the program was as follows:

The President's Report Dr Frank Overton

The Committee on Public Health

Dr A G Terrell

The Committee on Children's Clinics

Dr David MacDonell

The Committee on General Hospitals

Dr W H Ross

Anti-Tuberculosis Work Dr E P Kolb

Reports of allied organizations were given as follows:

Anti-Tuberculosis Fund Work, Mrs Mary Weaver Blanchard, R N Supervisor of County Nurses

Official Public Health Work, Dr M D Dickerson, District State Health Officer

Children's Consultations, Miss M Farquhar, R N, District State Supervising Nurse

The County Tuberculosis and Public Health Association, Dr W H Ross

Child Welfare Work, Miss Ruth Newman, Supervisor, County Board of Child Welfare.

While the County Medical Society meets only twice a year on account of the geographic distribution of its population, groups of doctors were meeting once or twice a month in connection with the general hospitals, one of which is located in each corner of the County. Reports from each group were given.

Dr W H Ross reported that the group centering in the Southside Hospital at Bay Shore numbered about 40 doctors who met twice monthly, once at a staff meeting of the hospitals and again as the South Side Clinical Society. The success of the Society is due largely to its program, which consists of a social supper at seven o'clock, followed by a scientific session.

Dr A G Terrell reported that the group centering in the Southampton hospital meets monthly at a staff meeting, and in addition, it holds several meetings which are both social and scientific.

Dr C C Miles, reporting for the group centering in the Greenport hospital, said that the doctors meet monthly in the hospital as a Staff, and that each takes his turn in entertaining the others at a social dinner at which a scientific paper is usually presented.

Dr W P Kortright reported that the Huntington Hospital group meets quarterly, and that attempts were being made to revive the Society which formerly met on one evening of each month.

The scientific part of the program consisted of a moving picture demonstration of the pathology of syphilis of the cardio-vascular system with special reference to aneurism of the aorta, by Dr Orrin S Wightman, of New York City, Editor-in-Chief of the NEW YORK STATE JOURNAL OF MEDICINE, and also of a brief report of an interesting case from each of the general hospitals of the County.

Dr Wightman's moving pictures illustrated the progressive effects of syphilis, the leucocytosis, the fibrosis, the destruction of the muscular tissue of the heart and arteries, the dilation of the cavities of the blood tubes, and the formation of the pouches called aneurism. His pictures were concluded by the demonstration of an aneurism as large as a child's head obtained from a patient last year in the City Hospital on Welfare Island. The pictures showed the patient with a bulging pulsating tumor in the chest wall of the site of the aneurism. Then followed pictures of the tumor mass obtained on the death of the patient three days after his admission to the Hospital. The tumor consisted mostly of the aneurism fused

with the heart and surrounding tissues. Its walls were over an inch thick, and the mystery was how the production of a loose clot and embolus was avoided.

Dr Wightman said that the tumor illustrated the end result which often occurred in untreated syphilitic conditions, but by proper diagnosis and treatment, the condition could be stopped in its early stages.

Dr Rodney E Wyman, representing the Staff of the Southampton Hospital described a case of multiple fractures of the pelvis, and showed x-ray plates of the parts and described the methods used to hold the two public bones in apposition.

Dr W P Kortright showed x-ray plates of cysts in the femur, tibia, and heel of a patient. The tumor had been diagnosed as benign and the patient's general health was good.

Dr Hallock Luce, on behalf of the Staff of the Greenport Hospital, described a case of acute pancreatitis.

Officers for 1928 were elected as follows:

President, Dr Frank S Child, Port Jefferson, Vice-President, Dr Edward R Hildreth, Bay Shore, Secretary, Dr Edwin P Kolb, Holtsville, Treasurer, Dr David H Hallock, Southampton, Censors, Drs David H Schenck, Southampton, Paul Nugent, East Hampton, William A Baker Islip.

New members elected were:

Dr Jacob Dramitzke, Patchogue

Dr Emil Edgar Falkenberg, Huntington

Dr Frank K Edgett, Amityville

Also Dr Gordon Priestman, Kings Park, by transfer from St Lawrence County.

## FRANKLIN COUNTY

The regular annual meeting of the Franklin County Medical Society was held at the Elk's Club, Malone, N Y, on October 26, 1927. The following members were present at the session: Dr L P Sprague, President, Dr G F Zimmerman, Secretary-Treasurer, Dr W N MacArtney and Dr F F Finney, censors. Members present: Drs Tobin, Dolphin, Kissane, Wardner, Harrigan, Blacklett, Smith, Stickney, Stamatiades, Stoughton, Van Dyke, White and Rush.

Visitors present: Drs James E Sadler, President, Medical Society of the State of New York, Poughkeepsie, Dr Joseph S Lawrence, Executive Officer, Medical Society of the State of New York, Albany, Dr John A Card, Vice-Speaker House of Delegates, Poughkeepsie, Dr M P Warmuth, Philadelphia, Pa, Dr H B Kurtz, Cleveland, O, Dr S E Appell, Dover Plains, N Y, Dr S W Sayer, District Sanitary Officer, Gouverneur, N Y, Dr S R Allen, Champlain, N Y, Dr Lyman G Barton, Plattsburg, Dr M Taylor, Edwards, Dr Samuel W Close, Gouverneur, Dr C A Northrup, Hermon.

In the morning a cancer clinic was held at the Alice Hyde Hospital under the direction of Dr John E White, who demonstrated the results of Glover's serum in cancer cases. This clinic was attended by physicians of Franklin and adjacent counties, and about thirty cases were shown.

Dinner was served at 1 30 P M.

The business session opened at 2 P M. Dr L P Sprague, President, presiding.

Two applications for membership were presented and approved, Dr C McConnell, Hoganburg, N Y, and Dr Bruce T Smith, Fort Covington, N Y.

Dr F F Finney submitted a verbal report on the progress of the examination of pre-school children. His report showed the inability of one health nurse to supervise the management of these examinations in the district. It was thereupon moved and seconded that the President draft a resolution to be presented to the Board of Supervisors with the purpose of appointing another health nurse for the county. Carried.

The following resolution was accordingly framed:

We, the members of the Franklin County Medical Society realize that one County nurse is inadequate for the needs of the county, that she is unable to do the necessary work, and we do hereby,

Resolve, that the Board of Supervisors of Franklin County provide another nurse to assist the present incumbent.

The following committee was named by the President to present the above resolution to the Board of Supervisors: Drs J E White, P F Dolphin and R G Perkins.

It was then moved by Dr Finney, and seconded by Dr Dolphin, that the Committee on Examinations of pre-school children be retained and the work go on for another year. Carried.

Committee: Drs F F Finney, Malone, C C Trembley, Saranac Lake, P E Stamatiades, Brushton.

Dr Dolphin in behalf of the Committee appointed to confer with Judge E C Lawrence about fees for lunacy examinations, reported that Judge Lawrence had set a fee of \$8 for examinations, and twenty cents mileage each way.

Following the business session the following papers were read:

1 The Necessity for Early Diagnosis in Cancer—Dr R G Perkins, Malone

This paper received very favorable mention by Dr Sadlier and his associates

2 The Activities of the Medical Society of the State of New York—Dr James E Sadlier, President of the Medical Society of the State of New York

Dr Sadlier in his able address strongly urged the physicians to impress upon their patients the importance of yearly physical examinations, to make universal the work which the Life Extension Institute can do only to a limited degree

He also urged that each society should be a unit in making an intensive study in one or more lines of original research

The subject of Public Health Relations was fully discussed and described in detail

Dr Sadlier finally urged that each society strive to secure in its membership every reputable physician possible

Dr J S Lawrence showed the importance of holding county meetings to discuss different phases of educational work He claimed we do not hold enough meetings The work of the Public Health Relations Committee was discussed, and at his suggestion the following committee was appointed by the President Drs MacArtney, Wardner, Kingston, Austin and Kissane

Dr J A Card, Vice-Speaker of the House of Delegates, followed Dr Lawrence and spoke on the annual registration of physicians and

urged all physicians to register immediately on receipt of their cards He also urged the importance of periodic health examinations as recommended by Dr Sadlier, and said, "There is no reason why we cannot make the examinations ourselves, instead of sending patients to the Life Extension Institute Dr Card's paper was discussed by Dr Sayer, who stressed the importance of a Public Health Relations Committee

Dr M P Warmuth of Philadelphia, Pa, in his address gave the reasons why he became interested in Glover's serum, and enumerated many cases which had been improved or cured by the cancer serum treatment during the past five years

Dr H B Kurtz of Cleveland, Ohio, supplemented Dr Warmuth's paper with a resume of the results he had obtained in the use of Glover's serum over a period of five years

Lantern slides of selected cancer cases were displayed

The following officers were elected for 1928  
President, Dr G M Abbott, Saranac Lake  
Vice-President, Dr P F Dolphin, Malone  
Secretary-Treasurer, Dr G F Zimmerman, Malone

Censor for three years, Dr J Woods Price, Saranac Lake.

Delegate to State Society, Dr C C Trembley, Saranac Lake, Alternate, Dr L P Sprague, Chateaugay

G F ZIMMERMAN, M D, *Secretary*

## QUEENS COUNTY MEDICAL SOCIETY

A regular meeting of the Medical Society of the County of Queens was held at the Queens Valley Golf Club on September 27th, 1927, at 8 30 P M, Dr Joseph S Thomas in the chair The minutes of the Outing Meeting held June 14th, at Harbor Inn, Rockaway Park, were approved as published

The following names having been approved by the censors were presented for election to membership On motion they were elected by one ballot cast by the secretary

George C Ames, M D, 18402 89th Street, Hollis

Jesse Badner, M D, 14617 Hillside Avenue, Jamaica

Louis W Granirer, M D, 8401 Boulevard, Rockaway Beach

Kate Freeman Miller, M D, 123 Alburtis Avenue, Corona

James Vincent Rizzi, M D, 9034 170th Street, Jamaica

The scientific session opened with an address by Clarence J Gamble, M D, on "The Stetho-

scope in the Diagnosis of Heart Diseases" It was accompanied by a Demonstration of Heart Sounds and Heart Murmurs through a Western Electric Stethoscope and Public Address System installed by the Bell Telephone Laboratories

Speaking of the electrical stethoscope, Dr Gamble said, "One of the most difficult fields in medical instruction is the auscultatory portion of physical diagnosis Text book descriptions of lung sounds as 'like the swish of wind in distant trees' and the murmurs as resembling 'the escaping steam in an apartment radiator' are the unsatisfactory means by which the printed page attempts to convey to the novice what he will hear in a patient Medical schools find it difficult to provide the necessary number of patients and variety of conditions to give the student the basis he should have for this diagnostic work

"It is chiefly for the purpose of meeting this difficulty that the electrical stethoscope was designed by the Bell Telephone Laboratory

Using the vacuum tube so well known in its radio applications, provision has been made for magnifying sounds coming from a patient's chest so that a class of as many as 500 may listen simultaneously. In this way, with a minimum of effort in securing patients to illustrate a particular condition and with a great saving in time both of the instructor and of the student, classes may now be given a better grounding in the art of physical diagnosis than has previously been possible.

"As usually used the electrical stethoscope is provided with a telephone receiver for each listener to which he connects the tube of his own stethoscope. For the demonstration at the meeting of the Queens County Medical Society, the electrical public address system, also developed by the Bell Telephone Laboratories, is used for additional magnification. The combination of the two makes possible an increase in power of the vibrations of the patient's chest 1,000,000,000,000 times, the resulting sounds issuing from two large horns six feet across, and filling the entire room with an accurate imitation of the heart and lung sounds.

"One advantage which the electrical stethoscope makes possible is the use of electrical filters. By turning a switch on the instrument, all the vibrations either above or below a chosen point may be eliminated. This makes it possible to decrease the intensity of the first and second sounds and brings out the murmurs in a way which can be appreciated much more readily by the novice. After the students have recognized the murmur and located its time, the filters may be cut out, allowing them to hear it in its usual proportions.

"The electrical stethoscope is now in use in

more than fifteen of the medical schools of the country. Its designers are working on a small portable model which it is hoped will be of great use to the deaf physicians.

"A further improvement in the teaching of physical diagnosis which the electrical stethoscope has made possible is the production of phonograph records of heart and lung sounds. During the past winter a series of records of typical heart murmurs were produced at the Columbia Phonograph Laboratories. Experimental work is now being done with a special reproducer for these so that they may be heard through the physician's own stethoscope head piece. As soon as this is completed the records will be available for all physicians and medical students."

In the demonstration which followed, Dr Gamble made use of a considerable number of heart cases from the cardiac clinic of St John's Hospital, Long Island City. The heart sounds were of such magnitude that they were heard not only by the audience in the room, but throughout the entire floor of the club building in which the demonstration was made.

Dr J. A. Smith of Elmhurst, Secretary of the American Heart Association, addressed the meeting on the Motion Picture Demonstration of the American Heart Association, "The Valves of the Heart in Action," following which the pictures were exhibited.

At the close of the meeting a vote of thanks was passed to the speakers, Drs Gamble and Smith, for their entertaining and instructive presentations and to Dr Prest and the Queensboro Tuberculosis and Health Association for their arrangement of the program of the evening.

E. E. SMITH, *Secretary*

## REGISTRATION OF PHYSICIANS

The application cards for the registration of physicians were mailed in September with the expectation that all of them would be filled out and returned before the first of January. For a time they came in rapidly, but lately they have been coming in much more slowly. We have received only 10,000 applications out of a total of over 17,000. The first of January is not very far away and applications must come in much more rapidly than they are now coming in if we are to register everyone on time. We have already issued and mailed about 9,000 registration certificates and are continuing to send out these certificates every day. We want to send the list to the printer as soon after the first of January as possible, but cannot do so unless the

physicians of the State cooperate so that all the applications will reach us before the first of the year.

We are trying to make registration a success with as little trouble to all parties concerned as possible. We welcome criticisms and suggestions, and hope that every physician who fails to receive his registration certificate within a reasonable time after his application, will let us know at once. We feel sure that with everyone co-operating to the best of his ability, an accurate and complete list of registered practicing physicians can be prepared and distributed.

CHARLES B. HEISLER,  
*Assistant in Higher Education*  
*State Department of Education*

## CATTARAUGUS COUNTY

The Committee on Public Health and Public Relations of the Cattaraugus County Medical Society made the following report and recommendations on October 28, 1927, concerning a County Health Department

### RECOMMENDATION A

That at the Fall or Annual meeting of the Board of Supervisors of the County of Cattaraugus the following suggestions be formally presented by the Society to the Supervisors of Cattaraugus County

#### *Suggestion No 1*

That, as the terms of office of the present members of the County Board of Health expire by termination or resignation, physicians be appointed to these positions, until a total of five physicians shall be reached, and it is further suggested as a part of the above that the physicians appointed shall be nominated for appointment by the Medical Society of Cattaraugus County, and shall be licensed and registered physicians, resident in the County (Such a procedure is permitted by the State law governing county boards of health, the law merely providing that there shall be *at least* two physicians on the county board of health)

#### *Suggestion No 2*

That there be constituted by the Board of Health of the County of Cattaraugus an ADVISORY COUNCIL, to serve without fees or other remuneration, with an unofficial status, and with the provisions that

- a The membership of the ADVISORY COUNCIL shall be as follows  
Ten physicians nominated by the county medical society

Two dentists nominated by the dental organization of the county

One registered nurse, active or retired, but not at the time of her appointment or afterward engaged in county public health work

One doctor of veterinary medicine, engaged in the private practice of his profession in the County

Two ex-officio members, viz, the president of the County Tuberculosis and Public Health Association, and the District State Health Officer supervising this County

- b The duties of the advisory council shall be as follows

They shall assist and counsel the County Board of Health in the development of policies and programs. They shall lend support to the County Board of Health as indicated, and aid in the interpretation of its activities to the public

- c At no time shall the County Board of

Health be legally bound by the advice of the advisory council

- d In the event that any fund, foundation, association, or other philanthropic organization shall signify its desire to disburse in this County any sum or sums of money for the advancement of public health or the demonstration of the advantages thereof, it shall be the function of the advisory council, following proper action by the Board of Supervisors and the Board of Health of the County, to act as the supervising agent in such disbursement or demonstration, and in the development and exercise of this function, the advisory council may be enlarged as to membership by the addition of the following

Two representatives of the Fund, Foundation, Association or philanthropic organization contributing the money

One representative of the Committee on Public Health of the Medical Society of the State of New York

One representative of the Department of Health of the State of New York

#### *Suggestion No 3*

That the Board of Managers of the County Sanatorium be abolished, and their duties and functions be incorporated in those of the County Board of Health, if permitted and provided for by law

#### *Suggestion No 4*

That the Board of Managers of the County Laboratory be abolished, and their functions and duties incorporated in those of the County Board of Health, if permitted and provided for by law

#### *Suggestion No 5*

That, contingent upon acceptance by the County Board of Health of the plans outlined in Suggestion No 2, the Board of Supervisors of the County of Cattaraugus appropriate for the ensuing year for the purposes of the County Board of Health, exclusive of the amount for the County Sanatorium, the sum of \$18 000 and that the terms of the resolution shall request a similar amount in the form of State Aid, with a total budget for the County Board of Health of \$36,000, as compared with a total for the present year of \$56,000, and in connection herewith the following budget is presented

#### SALARIES

County Health Officer, full time	5 000	
Clerk-Stenographer	1 200	
5 field nurses @ \$1,800	9 000	
1 sanitary inspector	1,800	17 000

## RENTS, ETC

Rent, main offices	1,200	
Rent, district stations (to be denoted)		
Telephone, telegraph, etc	300	
Postage, etc	300	1,800

## AUTO OPERATION

Mileage on health officer's car, at 8 cents per mile, the car to be provided by the health officer, with upkeep, insurance, etc, to be carried by himself (10,000 miles allowed)	800	
Depreciation on the cars of the nurses and sanitary inspector, the cars to be owned by the individuals operating them, and to be paid for by the county at the rate of 1/36 of the value of the car as depreciation each month, 6 cars, total depreciation per year	1,300	
Mileage for 6 cars @ 5 cents per mile (10,000 miles per year per car)	3,000	5,100

## SUPPLIES, ETC

Office supplies	1,500	1,500
Travel (out of County)		
For County Health Officer	150	
For 4 nurses to attend annual conference	200	350

## LABORATORY

Salary, bacteriologist	2,600	
Salary, clerk-assistant	1,200	
Salary, part-time director	900	
Telephone, etc	250	
Supplies	1,200	
Special contingent fund	500	6,650
For fees and other expenses of infancy, maternity and child hygiene clinics	1,000	1,000
For fees and other expenses of venereal disease clinics	1,000	1,000

For fees and other expenses of tuberculosis clinics	500	500
General contingent fund	1,100	1,100
Total		36,000
One-half in the form of State aid		

*Suggestion No 6*

That the Board of Supervisors appoint a committee, or empower its Committee on Public Health to confer with the County Board of Health and the Advisory Council, as to the possibility of providing emergency stations or hospitals, for the proper care of those cases of difficult labor occurring at points in the county at times inaccessible to the regular hospitals

*Suggestion No 7*

That the position of director of the County School Hygiene District be abolished, or if this is legally impossible at this time, that the appropriation therefor be made nominal

*Suggestion No 8*

That, at the end of two years a formal hearing be held by the Board of Supervisors, as permitted and provided for by law, and that, if the County Board of Health be then considered unnecessary, it be abolished

## RECOMMENDATION B

That the actual details of the development of policies and programs in connection with the County health work in Cattaraugus County be left to the advisory council and the County Board of Health

## RECOMMENDATION C

That since it is the firm conviction of the Medical Society of the County of Cattaraugus that there are in Cattaraugus County local physicians qualified for the position of county health officer, the Board of Health of Cattaraugus County be hereby asked to use every means to obtain for Cattaraugus County a county health officer who shall be a local physician, with experience in preventive medicine, and with a practical knowledge acquired through private practice in Cattaraugus County

# MEDICAL WARES

## LOOSE LEAF REFERENCE BOOKS

A physician keeps his professional knowledge up to date from three sources

- 1 From oral instruction
- 2 From medical periodicals
- 3 From text-books

Oral instruction by means of formal lectures or informal conversations is still the most widely used of all methods of imparting or getting information. It is also the most efficient for it permits the teacher to utilize the latest information on his subjects. The printed page soon grows old and a text-book on science needs revision by the time it is on the market. A physician hesitates to pay twenty-five dollars for a text-book of which a new edition appears every two or three years, he prefers to spend his money on lecture courses and on visits to clinics where he can talk directly with his teacher and ask him questions face to face.

A text-book on a scientific subject is based on fundamental facts which remain unchanged amid new discoveries. When it is revised, only about five per cent of the old matter is changed, and five per cent of new matter is added, while ninety per cent of the book remains unchanged. If the permanent matter of a text-book could be retained and the revisions could be inserted in their proper places, a great economic gain would result, besides the satisfaction which the owner feels in knowing that his book always contains the latest information.

The loose leaf system is the solution of the problem of keeping a text-book up to date. A subscriber to the system receives the latest complete volumes, and every six months afterward he receives new leaves to be inserted in place of those to be removed. The new leaves are numbered to correspond with the old ones, and the text is made to read continuously with that of the older leaves.

Much research and experimenting was required in order to devise a binder that was satisfactory, but loose leaf books are now made which are flexible and which open as flat as those bound in the ordinary way. Moreover the binders are easy to operate, and the old leaves readily stay in their places while the changes are being made.

An extensive editorial system is required to keep a loose leaf system up to date. A staff of research workers and editorial writers must be

maintained and the authors must be on the watch to catch and verify every item of progress. The reputation of the publishers would be impaired if an important item were missed in the semi-annual distribution of new leaves. On the other hand, the premature announcement of an alleged discovery which turns out to be worthless or discredited will be quickly fatal to the reputation of the book. A physician buys a loose leaf system on the good reputation of both the publishers and the authors, with the assurance that the information which he receives is that of the current year.

Since the publishers maintain a staff of editors and authors, they are in a position to give replies to inquiries made by the owners of the books. This service is a stimulus to research, for questions are always inspiring to authors and research workers. Publishers profit by a knowledge of what their patrons want to know, and authors are led to explain points which otherwise might have been left obscure.

The question and answer service is of great value to the physician who is engaged in research work or is preparing a paper for the instruction of his colleagues. It is the nearest approach to the oral method of imparting instruction with its personal contact with noted teachers.

The loose leaf system is peculiarly well adapted to text-books embodying encyclopedic knowledge in medicine, surgery, public health, and other branches of medical practice. Such complete articles have a special appeal to physicians, for the law presumes that every doctor treating a case shall make use of the latest information relating to the patient's disease, the price of a loose leaf system and the service of answers to questions is an insurance paid as a protection against a possible charge of neglect to apply every available procedure.

Physicians are also interested in loose leaf encyclopedias on general subjects. Every person who buys a large encyclopedia is soon urged to buy supplemental volumes in order to keep the information up to date. The loose leaf system enables the owner to insert the new matter in its proper place where it will be readily available.

Loose leaf Bibles are also published for the benefit of preachers and research workers who wish to insert information regarding particular chapters and verses.

## ACCEPTANCE OF MEDICAL ADVICE

Responsibility for a failure to cure lies with the patient or his family quite as often as with the doctor. If the prescription of the doctor is not followed, he cannot effect a cure. Inability as often as unwillingness accounts for failure to take a doctor's advice.

A great variety of conditions prevent a patient from profiting by medical advice. There are poverty, and a natural disposition of pessimism, there are laziness and over indulgence in the whims of the patient, and there are stinginess and greed and above all, ignorance. Any of these conditions may render futile the attempts of the best doctor to cure a patient.

The *New York Herald-Tribune* for November 14 contains the announcement of the Presbyterian Hospital of New York City, that an expert worker in the social service department will study the traits and inclinations of the patients in order to meet their peculiarities and adapt the treatment to the special conditions of the patients and their families. Miss Hamilton, the worker in charge of the service is quoted as saying:

"A study of a patient's traits and inclinations is necessary to establish the true state of his health. Her classification lists these modern social symptoms under the general heading of 'Symptomatic Behavior Attitudes or Reaction Modes'. This, in turn, is divided into two parts listing certain traits under 'Delinquency' and 'Unconstructive Personality Traits'. Bootlegging, perjury, non-support, forgery and arson are among the classifications in the 'delinquency' column.

"Extremes of characteristics, whether normally good or bad, are listed as 'Unconstructive Personality Traits'. They include such opposites as rebelliousness and resignation, dependence and hyper-independence, boasting and discouragement.

"The important part of the new medical social terminology is that now, for the first time, all these traits are actually named," said Miss Hamilton. "Now the social service worker knows what she is treating. Previously, only broad generalizations were used in defining the findings of the social service worker, such as 'desertion,' 'old age' or 'mental illness'."

"The classification, according to its author, will aid not only an immediate diagnosis of a patient's social ills, but enable physicians and social service workers to correlate and study together their joint conclusions."

A variation of the same theory is that the absorption of toxins may produce a changed behavior. A case evolving that principle is reported in the *New York Herald-Tribune* for November 11, in which a young man accused of a hold-up was treated and his criminal tendencies were pronounced eradicated by two physicians. The account says that the medical testimony was that "sinus trouble had caused a partial cessation of circulation in Lyle's brain, causing criminal propensities. Several witnesses testified to the youth's character. Magistrate Croak then reduced bail and put the case over on condition that Lyle should undergo treatment and report to him at frequent intervals.

"After the sinus operation it was found that even more serious trouble required treatment. Subsequently Lyle submitted to the removal of his tonsils and five abscessed teeth, operation for intestinal trouble and treatment for abnormal blood pressure.

"Lawyers familiar with the case pointed out that Lyle's submission to the treatment was in itself an admission of guilt. It was also said that he has not denied committing the crime. In view of this it was felt that he could hardly escape being found guilty and receiving fifteen years under the Baumes law."

## OPEN THE GARAGE DOORS

The *New York Sun* of November 10 is to be commended for printing the following warning against carbon monoxide poisoning in closed garages:

"Alongside the man who rocks the boat and his partner in foolhardiness who didn't know it was loaded, place must be made for the motor car operator who shuts the garage door and leaves the engine running. Deadly carbon monoxide gas pours from the exhaust pipe, and the result is inevitable.

"Cold weather favors the folly of those who refuse to take heed of this danger. They wish to tinker with the car and they think they will keep warm while they are at work. The result is that if they are lucky they expose themselves only to serious prostration. If they are not children of good fortune, death is the penalty they pay for their neglect of elementary caution.

"Not all the motorists guilty of this practice are novices. Some of them have had sufficient

experience to teach them that the combination of an unventilated room and a running internal combustion engine is fatal. Carbon monoxide

plays no favorites. It kills beginner and old timer impartially, and the closed garage door is its principal assistant."

---

## UNFULFILLED PREDICTIONS

Medicine as well as politics has its unfulfilled predictions. Bruce Barton, who always speaks an encouraging word, says in the *Sunday Herald-Tribune* magazine of October 30:

"The first time I saw him he stood on the platform facing a great audience of college students. He was thirty-three years old. Stretched across the wall behind him was a big blue banner with this legend: 'The redemption of the world in this generation.'"

"That multitude of ardent young spirits drank in his oratory eagerly. They were impatient with the bungling delays of middle-aged folks who had been conducting human affairs. They wanted no more delays, no fooling, they would get the world saved right away—now."

"Eighteen years have passed, and if the millennium has come, news of its arrival was not printed in the particular paper which I happen to read."

"I saw my friend the orator only a few days ago. He is fifty-one years old and head resident of a social settlement."

"He no longer talks about the redemption of the world in this generation. He is reconciled to the fact that human nature is pretty stubborn stuff, requiring a long period of complete purification."

"He is content to gather in the handicapped boys and girls of his slum neighborhood and give

them a chance to grow strong in his gymnasium. He conducts evening classes where they learn at the close of their day's work. In a quiet way he holds up before them ideals of useful living."

'At fifty-one he has dropped the illusions which were so glorious at thirty-three. But the faith of thirty-three remains. He still knows the battle will be won, though victory be several hundred or a thousand years away, and loyally, obscurely, he fights the good fight.'

Youth which knows no history, comes romping into the world determined upon immediate results. The headwaters of the river of life are fed with pure cold streams of melted snow from the mountain tops.

"The test comes not in youth but in the middle years when the stream runs slower, when it is a little soiled by hard contact with the banks, when—being often diverted from its course to turn wheels and water farms—it plods more wearily to the sea."

"Happy are they who, traveling more slowly, yet travel with sturdy hearts, who, having lost the illusions of youth, still have kept the faith."

Dr. Barton might have made his friend say: "No tuberculosis in 1930." He might also have said: "Happy are the physicians who having lost the illusion of universal physical salvation, still keep the faith and travel on with sturdy hearts."

---

## HAIR GRAFTING

Baldheaded people are fair marks for those who profess to have the secret of hair restoration, but, the actual demonstration of new hairs fixed to bald spots brings hordes of patients eager to part with their money. The following account in the *New York Sun* of November 13, although of humorous intent, yet is worth hundreds of dollars to the manager of a certain beauty parlor. The account begins:

"A little band of dauntless scientists gathered in a knot today and implanted the first hairs that have ever been affixed to a bald spot in America."

"Up in a rear room of a beauty salon with only about twenty reporters and photographers grouped around, the secret demonstration took place, with hardly anybody daring to believe his eyes."

"By Jove, doctor!" gasped a man from the most serious of all the metropolitan dailies, "you've done it! Accept my congratulations."

The story ends with an account of the operation and says:

"Eighteen years ago he first covered a Norwegian scalp, but not sufficiently to satisfy him, according to his son, and he has been working at it ever since. Gradually he got better, and now he can make a completely bald man thoroughly hirsute in three months, two hairs at a time."

'At this rate the occupants of the first four rows at the Follies would be covered up in about thirty years, provided the doctor reached them before they died.'

"By the way, the operation is performed by fixing two root ends of hair into a gold ring, pressing the hair through a hollow ring down the hair canal and removing the needle. The gold ring and the hair remain. The hair does not grow, fall out, turn white or whistle."

Several witnesses testified to the youth's character. Magistrate Croak then reduced bail and put the case over on condition that Lyle should undergo treatment and report to him at frequent intervals.

"After the sinus operation it was found that even more serious trouble required treatment. Subsequently Lyle submitted to the removal of his tonsils and five abscessed teeth, operation for intestinal trouble and treatment for abnormal blood pressure.

"Lawyers familiar with the case pointed out that Lyle's submission to the treatment was in itself an admission of guilt. It was also said that he has not denied committing the crime. In view of this it was felt that he could hardly escape being found guilty and receiving fifteen years under the Baumes law."

## OPEN THE GARAGE DOORS

The *New York Sun* of November 10 is to be commended for printing the following warning against carbon monoxide poisoning in closed garages:

"Alongside the man who rocks the boat and his partner in foolhardiness who didn't know it was loaded, place must be made for the motor car operator who shuts the garage door and leaves the engine running. Deadly carbon monoxide gas pours from the exhaust pipe, and the result is inevitable.

"Cold weather favors the folly of those who refuse to take heed of this danger. They wish to tinker with the car and they think they will keep warm while they are at work. The result is that if they are lucky they expose themselves only to serious prostration. If they are not children of good fortune, death is the penalty they pay for their neglect of elementary caution.

"Not all the motorists guilty of this practice are novices. Some of them have had sufficient

# BOOK REVIEWS

**RÖNTGEN RAYS IN DERMATOLOGY** A Handbook for Practitioners and Students By L. ARZT, M.D., and H. FUHS, M.D. Octavo of 202 pages, illustrated. New York, William Wood and Company, 1927. Cloth, \$6.00.

The dermatologist of today who is not conversant with the technique of therapeutic radiation and prepared to apply it in his office denies to many of his patients one of the most efficient remedies, and, in many instances, stands between his patients and their welfare. McKee, in his splendid work, pointed out that there were practically four score conditions or diseases of the skin wherein radiation might be applied with benefit. In the book at hand the authors have drawn on their long and varied experience to instruct the reader in the proper application of radiation in a majority of the conditions which Dr. McKee enumerated. In practically all of their treatments filters of aluminum of varying thickness are advised and their reasons for so doing seem logical and proper. The first chapters deal with the physics of X-rays, dosage and the methods of exposure, the remaining chapters with the application and dosage of individual diseases. An appendix is added for quick reference and presents the list of diseases of the skin in which radiation is applicable in alphabetical order. We are indebted to the translator and publisher in making available to English speaking physicians the technique and experience of our German colleagues. N. T. BEERS

**INTERNATIONAL CLINICS** Edited by HENRY W. CAYTELL, A.M., M.D. Thirty-seventh Series, Volume 1. Octavo of 304 pages, illustrated. Philadelphia and London, J. B. Lippincott Company, 1927.

This issue opens with an article on diabetes mellitus by Dr. Barker. Much of the old data concerning diabetes is presented, and a considerable review of the literature of today is mentioned. When Dr. Barker comes to the dietetic treatment of the disease he sidesteps the problem, and refers to Dr. Joslin's book. Such articles could be made of infinitely more value to the practitioner if the authors devoted less time to things well known and more to the less well known. Few physicians know how to manage the diet of such patients. So much attention is given to things of second importance in this article that things of first importance are passed over quickly. Diathermy is discussed at good length, as well as the venereal disease problem as a whole. This number contains many articles of interest and concludes with a review of the progress of medicine in 1926, which is decidedly worthwhile. J. ARTHUR BUCHANAN

**SEGREGATION AND AUTOGAMY IN BACTERIA** A Contribution to Cellular Biology. By F. H. STEWART, M.A., D.Sc., M.D. Octavo of 104 pages, illustrated. London, Adlard and Son, Ltd., 1927. Boards, 7s. 6d. Net.

The author's subtitle "A contribution to cellular biology" is an indication of the content of this work. It is a painstaking, minute study in advanced bacteriology and biology, summing up the work of previous observers, and the results of the author's research (based on over 10,000 cultures) to prove that bacteria pass through a life cycle with alternating phases of a sexual and asexual reproduction.

Bacterial variation and mutation, the author contends, are similar to those in higher plants and animals, and best explained by the Mendelian principles. On this premise, the author maintains that observations and experiments on the growth of bacterial colonies support the theory that bacteria go through a life cycle as in protozoa.

ISIDOR COHN

**AN OUTLINE HISTORY OF OPHTHALMOLOGY** By THOMAS HALL SHASTID, A.M., M.D. Octavo of 34 pages. Southbridge, Massachusetts, American Optical Company, 1927. Cloth, retail price \$1.25. Selling Agent: George Wahr, Ann Arbor, Michigan.

It does not seem possible that anyone would be willing to continue long at his life's work without some knowledge of the history of its progress. Indeed, it would seem well nigh impossible that anyone can practice ophthalmology intelligently without at least enough of the romance of the development of the science to supply perspective to his work. "An Outline History of Ophthalmology"—by Thomas Shastid—certainly supplies a need. It will, doubtless, arouse some of the latent interest which only needs a moderate stimulation.

The Outline History is particularly valuable because it appeals to the romantic. Few of us look back on our school studies in history because it meant to us the amassing of a great amount of more or less correlated facts in their chronological order. Perhaps such a training has a very definite value, but the impressions gained are often poorly retained because they lack color. After all, the general impression is all that we can expect to keep. If we realize that such and such a period is represented by a high degree of culture and that this was followed by a period of the worst sort of chaos—if we can form in our minds a reason for this often followed sequence, we have something much more useful than to remember that Pope Leo X wore a concave pair of spectacle lenses in 1517.

A few high lights are very attractively presented. Who, for instance, would not be interested in "Babbage, the Unfortunate," Helmholtz, etc.?

Our final impression of the whole outline is a particularly satisfactory one and it is continually obvious that ophthalmological progress only began as it has continued, through the efforts of the physician alone.

JOHN N. EVANS.

**PRACTICAL MATERIA MEDICA AND PRESCRIPTION WRITING.** By OSCAR W. BETHEA, M.D., Ph.G. Fourth revised edition. Octavo of 498 pages, with illustrations. Philadelphia, F. A. Davis Company, 1926. Cloth, \$4.50.

This valuable book is completely revised and conforms with the standards of the U. S. P. X.

Part I deals with Materia Medica, giving the physician those essentials that are particularly vital to him regarding the drugs now employed and disregarding those that are no longer used.

Part II takes up the subject of Prescription Writing from all angles, is complete in every detail, and treats of Medical Latin, Choice of Vehicles, Percentage Solutions, Saturated Solutions, and many other topics necessary for the prescriber to know.

Part III, illustrated, giving the incorrect and correct forms of prescription writing, and showing not only the many pitfalls but the way to write formulae of sound therapeutic merit. This is one of the most practical books on this subject and well worth reading. S. F.

**MANUAL OF MEDICINE.** By A. S. WOODWARD, C.M.G. Third Edition. 12mo of 523 pages. London and New York, Oxford University Press [1927]. Cloth, 4/5 (Oxford Medical Publications).

In this volume there is a large amount of valuable knowledge put down in a very orderly and concise manner. Each system is taken up separately, and the more important points are indicated by large type.

The treatment is put down in one, two, three order and embodies all the modern accepted ideas. We can heartily recommend this latest revision. KENNETH McILVINE

# BOOKS RECEIVED

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.

**A TEXT-BOOK OF PHYSIOLOGY** For Medical Students and Physicians By WILLIAM H. HOWELL, Ph D, M D 10th Edition, revised. Octavo of 1081 pages, with 308 illustrations Philadelphia and London, W B Saunders Company, 1927 Cloth, \$6.50

**APPLIED BIOCHEMISTRY** By WITHROW MORSE, Ph D 2nd Edition, revised Octavo of 988 pages, with 272 illustrations Philadelphia and London, W B Saunders Company, 1927 Cloth, \$7.00

**INSURABILITY PROGNOSIS AND SELECTION** Life—Health—Accident. ## ZINC STEARATE BABY POWDER

The danger of fatal pneumonia following the inhalation of baby powder containing zinc stearate is discussed in the September Journal of the Medical Association of Georgia in an article by Dr L H Goldsmith of Atlanta. The *New York State Journal of Medicine* carried an editorial warning against baby powders in the August 15th issue.

The principal dangerous constituent in baby powder is zinc stearate, which acts mechanically and not chemically. Its particles are extremely small and light and tenacious, and enter the lungs readily, and then cause a swelling of the mucous membrane and asphyxia. Dr Goldsmith says in his article:

"One similarity in practically all cases, is the manner of the beginning of the onset. The baby is playing on the bed, or the floor, and is given the powder can to play with. On account of the powder being very porous and fluffy, it is necessary to have large perforations in the top. The baby attempts to put the open top in the mouth and receives a shower of powder in the mouth and nose. Sneezing and coughing is followed by crying, all of which tends to aspirate the substance deeper into the trachea and lungs.

"The diagnosis depends primarily upon the history. If there is the usual story of the baby having had the powder can for a toy, with subsequent coughing, sneezing and presence of powder on the face and in the mouth, the diagnosis is evident."

The subject is of so much importance that a committee was appointed by the American Medi-

cal Association to study the problem. The committee made the following recommendations:

"First, that all manufacturers of zinc stearate powders for infants be requested to use a self-closing container, and to place a uniform caution label on the container. Second, that its use as a dusting powder for infants be discouraged by the medical profession, because of lack of therapeutic evidence of its value."

The suggestion was made that the containers of zinc stearate powder have a self-closing top, an unattractive color, and a warning label. The article says:

"Usually the mother will give the child anything to play with if it is crying. The bright top attracts him and he will inhale the zinc stearate powder with, as a rule, very serious results. If we can discourage the use of the zinc stearate powder, we will do a very great deal. If we will try to instruct the mothers that they insist on a proper label on zinc stearate, it will do good. I am sure the committee will discourage the use of it. We cannot prevent the manufacturer of it, but we can advise the mother of the danger and in this way accomplish a good deal."

The article said that the manufacturers were approached by the A M A committee but did nothing about adopting a safety stopper. On the contrary, the makers of toilet powders used billboard advertising pictures showing babies pouring the powder over their bodies. While the dangerous constituent is stearate of zinc, yet mothers do not know what is in toilet powders, and so they should be warned against letting babies play with any toilet powder. Doctors also have a responsibility to warn mothers.

## PRENATAL PROBLEMS

The following quotations regarding prenatal problems are taken from an article by Dr Paul Appleton of Providence in the November issue of the *Rhode Island Medical Journal*:

"First, let us consider the mental side of the patient. She comes to us not as a test tube to a laboratory, but as an individual. She must be guided and treated as an individual and not as a hypothetical case. She has some real misinformation. She has many questions uncertain in her mind. She has fear. These matters must be sought out and cleared up—all of which takes time and unceasing patience. It is well worth

it, and will help tremendously in our management of the case.

"Get interested in the patient's life, her medical and social history, her ambitions, her ideals, and her attitude towards prospective motherhood. Emphasize her loyalties. Minimize her distrusts. Take away her burdens of worry and anxiety, and imbue her with optimism. She cares little for the diplomas on your wall. She knows little of your training, but she absorbs your personality, your sympathy and your kindly guidance. She can be led into an attitude of co-operative

(Continued on page 1342—adv rxv)

(Continued from page 1342—adv xvi)

logical experiences and trauma resulting in possible pelvic deformities

"Psychic disturbance is to some degree always present in pregnancy. Not always a depression. Sometimes a definite euphoria. It is so well known that it deserves little comment save this interesting observation, that almost all psychic disturbance fades away gradually during the last three or four weeks, so that even minute evidences of psychic disturbance are absent at term. A psychosis that is present when the patient reaches term is to me an ominous sign and the patient will bear watching after delivery lest she develop a true puerperal insanity.

"The cardinal signs of pre-eclamptic toxemia are well known. Albuminuria, hypertension, headache, nausea, edema, epigastric pain, and retinitis with choked disc. Many cases show only a few of these signs, and any one of them is significant and should not be overlooked. Toxemia going on to eclampsia may occur with an essentially normal urine. Of course it is rare, but dependence upon urinalysis alone is a dangerous practice.

"The examination of the patient should be made in an unhurried way, systematically with a clear idea as to what the findings mean, basing them upon a common sense interpretation of their relation to pregnancy or delivery. This examination should be thorough. The patient respects thoroughness for she appreciates that her attendant is more valuable to her in proportion to his fidelity in physical observation. Any pathological findings should be repeatedly watched for progress or results of treatment. Consultations help tremendously in interpreting dubious findings, and patients regard consultation as a strength, not a weakness, on the part of their attendant.

"Just a word about blood pressure. Of course, its regular observation is synonymous with good prenatal study. It is remarkable how little the blood pressure of the patient changes throughout her pregnancy, so that any marked rise in comparison to her observed normal, regardless of any arbitrary limit, should call for painstaking search for other symptoms of toxemia and their interpretation regarding the gravity of the situation and its treatment.

"Pelvimetry is perhaps the most important part of prenatal examination. It is an accurate vital check on one of the prime determining factors of the patient's mechanical ability to deliver. The measurement of pelvis is a good habit, easy to acquire and does not involve expensive or complicated apparatus. Why so many practitioners, otherwise careful, look upon this as a difficult or unnecessary procedure is hard to comprehend.

## The Gold Medal Cod Liver Oil

The Sesquicentennial Gold Medal awarded at Philadelphia as a recognition of the high quality of

### PATCH'S FLAVORED COD LIVER OIL

At the Sesquicentennial Exposition held in Philadelphia last year, the E. L. Patch Co. was awarded the gold medal for "excellence of product."

This award is only one of the various forms of recognition which our product has received.

The recognition given to our product by the medical profession, after five years of clinical experience, constantly reminds us of our great responsibilities.

Here are a few reasons why Patch's Flavored Cod Liver Oil is dependable.

It is made in our own plants along the North Atlantic Coast, from FRESH LIVERS.

Every lot is biologically assayed. The vitamin potency is guaranteed.

The dose is small—a half teaspoonful for children or a teaspoonful for adults three times a day.

It is pleasantly flavored. Your patient will appreciate this feature.

Let us send you a trial bottle of this "Gold Medal Cod Liver Oil."

Taste it! You'll be surprised.

(Continued from page 1340)

effort and her entire pregnancy and labor, too, will be colored by this mental state. I know of no human experience where the doctrine of psycho-physical parallelism is more aptly demonstrated. One must of course be guarded in prognosis and one must interpret physical signs truthfully, but one may and should minimize groundless fears.

"One of the difficulties in handling these patients is the bridge-table advice that she gets from her neighbor. There are as many modern popular notions as there are old wives' tales, less superstitious in character but just as depressing to the introspective patient, and, let me emphasize, that pregnant women are more introspective than they will ever reveal. Search out these mental neoplasms that are causing anguish to the worrisome patient and extirpate them with a well chosen word of scientific fact to disprove, or radiate them with emanations of optimism. Patients may forget our skill, but they do not forget the milk of human kindness.

"I no longer advise patients for or against the maternity corset. The woman used to corsets will be more comfortable with one, but her sister unused to such restraint will be as comfortable without. A supporting binder or girdle will often produce some comfort.

"No less an authority than the late Dr. Robert W. Lovett, the eminent orthopedic surgeon of Boston is my reason for advocating the high heeled shoe in pregnancy. By tending to throw the patient forward, thereby changing her centre of gravity, she is forced to stand and walk more erectly, throwing back her shoulders and preventing round shoulders and other postural spinal curvatures. This tends to prevent tilting of the pelvis and favors the gravitation of the presenting part to enter the patient's pelvis. These shoes also give better support to the arches of the foot, already overtaxed by the increasing weight of the patient. I commend this matter to your attention.

"Dietary restriction is ill advised in early pregnancy. The patient is usually very hungry and often has unusual food desires and appetites. I believe in a full free diet, and in satisfying those naive cravings so often manifested on the basis that they represent a metabolic demand of one kind or another, too complicated often for the physiological chemist to interpret.

"History-taking is important, and care is essential. Detail to the point of exhaustion is ill advised. No patient is impressed by the game of 'Ask me another' in your office. It takes but a short time to get a skeleton history of the pertinent features bearing upon the problem of childbirth. The story of previous pregnancies, labors and puerperia is important as is that of gynecology.

(Continued on page 1343—adv xvii)

(Continued from page 1344—adv XXIII)

ways of doing some of the things. The subjects to be presented are not of equal importance in every county, the needs and the interests of people living in factory communities may be utterly different from those of rural districts. The mode of presentation, the diplomatic approach, and the self-interest appeal may have to be varied in order to capture the artisans in one district and the farmers of another. While plans for a more comprehensive program are in process of formation, tell us what your community requires.

'Local needs and local states of mind, as well as local facilities for cooperation must be considered, and we respectfully suggest that each county society shall provide some means of assistance in solving this educational problem. Whether you call it an educational, a public relations, or a welfare committee, matters little, the essential factor is that each component society should have a committee to advise about local needs and opportunities to assist in developing local campaigns and combining local influences, and to serve as contact agency between the society and the laity, not forgetting to utilize now as an intermediary in many instances the newly organized woman's auxiliary."

### MEDICAL GUIDANCE

How may a lay person be able to select and secure competent medical advice and attendance?

How may he determine who are competent physicians? How can he be assured that the doctor's services will reflect present-day medical knowledge?

These questions are discussed editorially in the November issue of the *Journal of the Michigan State Medical Society* which says:

"One editor advised us that not a day passes but what his office receives several such telephone inquiries. It is a problem presenting itself most pressingly for solution. We must assume that leadership. That is the reason we are inviting the attention and consideration of our members in order that their opinions may be utilized to reach a right solution.

"One suggestion is receiving considerable thought—local and district Medical Guidance Bureaus, where individuals may obtain dependable advice as to whom they can consult. This suggestion has much merit, still it is fraught with several valid objections so that the administration of such a Bureau can not now be outlined as to principles, policies or limitations. It must be experimented with and its possibilities closely and carefully investigated. We understand the Wayne County Medical Society has created some such Bureau and the people of Detroit are accorded the opportunity of applying to this Bureau.

There is nothing mysterious or ultrascientific about it. If one cannot measure pelves accurately, he is not doing his duty to the patient and should inform himself on this simple and vital matter. It is uncompromisingly essential that anyone undertaking an obstetric case should be thoroughly versed in this metric method and capable of interpreting the findings.

"The change in body weight of the pregnant patient is of some significance. During the first three months the weight is stationary or shows some loss, but during the last six months the patient gains about a pound a week. There is a good deal of scientific observation to support the contention that excessive gain in weight is almost a sure sign of toxemia, probably expressed as occult edema. Another interesting point, and this has been frequently borne out in my own experience, is that in the last three or four days of pregnancy, instead of a gradual increase there is a sudden change to a loss of weight amounting to about a pound daily. Many patients today possess bathroom scales of considerable accuracy, and where these are available one can, with the cooperation of the patient, keep a daily weight chart. When the peak has been reached and a sharp drop is noticed, the prophecy that labor is at hand is usually correct. There is a very valuable sign of impending labor.

"In conclusion, may I emphasize that when a patient goes into labor, there is nothing more satisfactory to the attendant than, having made a really careful study of the case from all angles, physical and psychological, he approaches the responsibility of her delivery with confidence and comfort? That confidence is contagious and is mirrored in the solace and equanimity of the patient as she faces her travail."

### MEDICAL EDUCATION

Education of physicians is receiving serious consideration in New Jersey judging by the following editorial in the October issue of the *Journal of the State Medical Society*:

"At the annual meeting of our state society, more discussion was aroused by the educational program than by any other one subject. Consensus of opinion strongly favored the continuance and further development of that program, but effective results are not to be obtained by merely voting adoption of a resolution and provision of funds. Progress will be slow and satisfactory results will scarcely be attained if the devising and promotion of a plan is left entirely to any one individual. It is not strictly a one-man job, even if he were employed to devote himself to that task exclusively. There are a thousand and one things to be done, there are many different possible

(Continued on page 1345—adv xix)

## UNSCIENTIFIC RADIO TALKS

The Journal of the American Medical Association for November 19, page 1786, contains the following information concerning radio health talks by quacks and takers

"Whatever else may be said of the quack and the faddist, they must be given credit for enterprise. The sheet anchor of the dispenser of pseudomedical buncombe, no less than of the out-and-out quack, is publicity. In the not very distant past, the quack and the faddist had the entree—at advertising rates—to the majority of the newspapers of the country, and thus was made the point of contact between sucker and suckee. But, gradually public opinion forced at least the better class of newspapers to be more circumspect in the space that they sold to those who offered panaceas for human ailments, and today the majority of newspapers of wide circulation do not cater to the business of the medical faddist or the quack. With that avenue closed, it became necessary for these gentry to seek other fields of publicity, and it was but natural that they should turn to the latest wonder of modern science, wireless telephony—the radio. This field had three elements in its favor: first, its novelty, second, the fact that the spoken word is even more effective than the written word in carrying conviction, third, and most important, that the business of broadcasting is in its infancy and its code of ethics is naturally low. Broadcasting in the United States is a commercial venture. Generally speaking, the broadcasting station is out to sell time on the air, just as the newspaper is out to sell space on paper. It is natural, therefore, that these stations should look with favor on any commercial organization that is willing to pay the price the station asks for puffing its particular line of goods. Thus it is that we who are radio fans have our ears assailed almost nightly with some

pseudomedical fad, or the exploitation of some crude piece of quackery. One of the earliest entrants into this field was the 'Palmer School of Chiropractic,' which has its own broadcasting station, WOC, at Davenport, Iowa, whose programs, unobjectionable in themselves keep before the radio listener the fact that there is an alleged educational institution devoted to the "science" of back-pushing. Then there is that enterprising quack who specializes on 'rejuvenation' operations and who practices, apparently, without let or hindrance by the state authorities, from Milford, Kansas—John R. Brinkley, who owns and operates KFKB Station WHT some months ago was broadcasting with great regularity the alleged virtues of a "patent medicine," Salicon, a preparation that the A. M. A. Laboratory found to be essentially a mixture of 3 grains of aspirin and 2 grains of magnesium carbonate. WJAZ, not so long since, was telling the radio world the marvels of that ingenious faker Professor Scholder, who professes to grow hair on bald heads, but who was unable to differentiate dyed twine from human hair. Over KTNT of Muscatine, Iowa, comes the story of the "Tangle Institute," which has a sure-fire cure for varicose veins, the invention, it appears, of one Dr. Charles L. Barewald of Davenport. WJBT of Chicago has described, via the ether, the marvels and virtues of the magic horse collar, the "I-on-a-co," of quack Wilshire. The Voice of Labor—WCFL—permits Dr. Percy Lemon Clark of Chicago, "a world authority on dietetics and food combinations," to broadcast health misinformation. Clark operates a "Health School" on "Sanatology" and tells the world that "acidosis and toxosis are the two basic causes of all disease. Over this same station—WCFL—comes also the "Restoro," a base imitation of Wilshire's magic horse collar, and possessing as much therapeutic value as an empty tomato can with a string tied to it.

## TWO SAFETY MEASURES IN CATARACT EXTRACTION\*

By WALTER S ATKINSON, M D, WATERTOWN, N Y

THE two measures selected for consideration are paralysis of the orbicularis, and closing of the wound with a suture or sutures

A forcible contraction of the orbicularis is probably the most common cause of loss of vitreous in cataract extraction. While a loss of vitreous is more or less expected in subluxated and dislocated cataracts, still a sudden contraction of the lid musculature in such cases adds greatly to the seriousness of it. To prevent this, various mechanical measures have been used, all of which are far from being infallible and offer many inconveniences

Methods of infiltration with novocain, and similar drugs, to block the impulses along the branches of the facial nerve, which supply the orbicularis, were advanced by Van Lint (1), and Villard (2), the principles being essentially the same

The method has been practiced by many operators who have reported very favorably on the procedure and, while pretty generally used, still many operators for one reason or another do not employ it

It is not my purpose to offer a new method but simply to support the principle;

Wright (3), in 1921, reported the routine use of this procedure with very satisfactory results. Wright (4) later reported blocking of the facial nerve at its point of exit from the stylomastoid foramen, but the occasional persistence of the paresis or paralysis for several months rather deters us from such a procedure in this country

Derby (5) in 1923 reported that he had adopted the infiltration with novocain for paralyzing the orbicularis as a routine

Robinson (6) called attention to the fact that the musculature varied in different patients and that the corrugator supercilii and the angular head of the quadratus labii superioris, acting in an accessory manner, caused forceful closure of the lids after the method of injection advocated by Van Lint and Villard, had been used, suggesting also infiltrating from the supraorbital notch

to the inner canthal ligament, following the contour of the bone, and another beginning at the infraorbital foramen and extending to the inner canthal ligament. In many patients this is not necessary but the aim should be to sufficiently paralyze the musculature of the lids so that the patient is unable to close them, whether one particular method or a combination of different methods be used to accomplish this result. When the lids are flaccid and partially opened, if the patient is asked to close his eyes as tightly as he can and the lids remain open and flaccid, or if one holds the lids open and the patient on being told to close as tightly as possible and no muscular contraction is felt, then one can proceed safely with the operation. This seems to be the safer indication to follow rather than using one method of infiltration and at the expiration of a certain time limit beginning the operation. Infiltration of the lids should, of course, be avoided. Some operators have said that they desire only a partial paralysis or a paresis of the lid musculature, but there seems to be no justifiable reason for such a desire. The more complete the paralysis the more desirable it is. The objection raised that with a complete paralysis the lids will not remain closed under the dressing is more fanciful than real. Operators using a complete paralysis experience little difficulty in this respect

Smith (7) states in regard to paralyzing the lid musculature with novocain, "it does away with the reflex contraction and reduces the muscle tone so that the lids tend to lie open, but the motor nerves are unaffected and the muscle remains under the control of will." He does not state what method of infiltration or blocking he used but certainly this has not been the experience of many operators using this procedure

Two per cent novocain, with one or two drops of adrenalin to 10 cc seems to be about the strength used by most operators. Some feel that it is safer to use one per cent novocain but a longer time is required before the paralysis is produced and very often it is not so complete. When one considers that the general surgeon uses 200 to 300 cc of 1/2% novocain in the ave-

of course, should be introduced before the section.

The objection to the Kalt (9) suture is that the wound is not covered by a conjunctival flap.

A modification by Verhoeff (10) of the Kalt suture, and later a modification of this, indicates his desire for a larger conjunctival flap.

To complete the section with a large conjunctival flap before introducing the sutures has the advantage of being easily and quickly done and with very little trauma. Then, provided the lid musculature has been paralyzed, little difficulty is experienced in introducing one central suture, the loops of which can be placed to either side out of the way, and the cataract extracted, the suture tied and two more introduced. With sutures placed nasally and temporally, if a good bite of the conjunctiva is taken, the wound at both angles can be closed very tightly at locations where iris prolapse are most likely to occur following combined extractions. The removal of the sutures need not cause uneasiness. If 00 silk is used they very often come out themselves by the 4th or 5th day and if not the irritation from such small sutures is slight, but they can be removed very easily and safely if just scissors without forceps are used, as suggested by Ziegler. This method of suturing the wound has proved to be the most satisfactory for me in the average case, but when the cataract is dislocated or subluxated, I prefer having the flap prepared and the suture in place before making the section.

With Berens' (11) untied suture, some raise the objection that the loops of the suture get in the way during the extraction of the cataract, but there need be only two, one on either side, and if the silk is wet they will lie flat and out of the way. Certainly the advantages greatly counterbalance the objections.

If some method of suturing is used where the suture is introduced before the cataract is extracted, the advantage of being able at any time to close the wound quickly and easily are so evident and so outweigh the disadvantages, that to consider them separately seems unnecessary. A needle holder without a catch adds greatly to the safety and ease with which sutures can be introduced, also a very fine sharp corneal needle, 14 mm long, with an easy curve makes the introduction much easier.

The forceps tying of sutures simplifies and facilitates the procedure, as well as being an added protection against infection.

A very simple way to tie with forceps is to grasp the lower end of the suture with tissue forceps held in the left hand, a turn of the suture is made around the end of the needle holder which is held in the right hand and the upper end of the suture is grasped with the needle holder and drawn through the loop made by taking this turn. The first of the tie is in this way made and the loops of the suture placed to either side out of the way. When the wound is closed and the first tie is drawn tight, a second one is made in the

same manner. In completing the knot, it is desirable to use tissue forceps instead of the needle holder. The fine 00 silk used in suturing often slips through ordinary tissue forceps unless the silk is grasped at right angles to the serrations on the tips of the forceps. This is most unsatisfactory and annoying but if tissue forceps, with a groove on one arm of the biting surface of the forceps and a ridge on the other arm that fits into the groove, are used, the finest silk may be grasped at any angle and will not slip.

### SUMMARY

Paralysis of the orbicularis in cataract extraction by infiltration with novocain to block the branches of the seventh nerve supplying this muscle is safe, easily produced, and makes the operation much simpler.

The object should be to get complete paralysis of the orbicularis and one should not confine himself to any one method of infiltration to obtain this end.

In uncomplicated cataracts it eliminates the most common cause of loss of vitreous.

It also helps to prevent serious loss of vitreous in dislocated and subluxated cataracts.

With the lids temporally paralyzed the introduction of a suture is made much easier.

Closing the wound with sutures is desirable and the advantages are many as compared with the disadvantages.

Sutures placed nasally and temporally help to prevent prolapse of iris.

A needle holder without catch, fine sharp needles, with 00 silk, and forceps for tying that do not allow the silk to slip, add to the ease and safety of the procedure.

rage case without ill effects, surely 6 or 8 cc of 2% novocain is well within the realm of safety. Labat (8) gives 30 cc as the amount of 2% novocain that can be used with safety on the average patient.

In fifty consecutive cases of combined extraction of cataract, some in capsule, where paralysis of the musculature was obtained by infiltration with novocain before beginning the operation, no vitreous presented except in two cases of loop delivery in subluxated cataracts, one with adhesions of the iris below. In these cases vitreous was expected but by drawing the wound closed with a suture which had already been introduced a loss of vitreous was prevented in one and in the other a small amount was lost. The visual results being 20/16 and 20/40, while forcible contraction of the lid musculature in these cases might have been disastrous. In another of this series the cataract was dislocated into the anterior chamber with secondary glaucoma, and was removed without vitreous presenting.

It is realized that with such a small number of cases one cannot draw very definite conclusions as to the desirability of the procedure. Still they help to demonstrate that in uncomplicated cataracts the loss of vitreous from squeezing is eliminated and also that a dangerous loss of vitreous is avoided in subluxated and dislocated cataracts.

The actual time from the beginning of the injection until the paralysis was accomplished was kept. The average time required for 1% novocain with adrenalin was 13.6 min. and with 2% novocain and adrenalin was 6.66 min. In a few paralysis occurred as soon as two and a half minutes. Each operator seems to vary the technique of injection somewhat to suit his individual characteristics, and provided the desired result is achieved without risk or undue discomfort to the patient, it matters very little what procedure he uses, but if a Labat syringe is used and a small wheal first raised with a No. 1 wheal needle, followed by the use of a No. 2 needle (5 cm. long) and injected slowly as the needle is introduced, one attains the desired result with the minimum amount of risk and discomfort. If the wheal is raised at about the center of the external orbital margin, the first injection made up the length of the No. 2 needle following the line of the external orbital margin and keeping as close to the bone as possible, then a similar injection down following the line of the external orbital margin, using about 2 cc. for each injection and necessitating only one puncture with the needle, the desired result is usually obtained. However, if not, further injection can be made along the orbital margin as suggested by Robinson. If after about ten minutes has elapsed with the paralysis not yet complete and not increasing, then further injections should be made at right angles to the course of the nerve supply to the orbicularis. While this is rarely necessary, still there is no particular

objection to it, except that it requires a little more time.

The fact that the course of the nerves supplying the orbicularis varies in different individuals, as does also the musculature, seem logical reasons for not depending upon any one method of infiltration if a complete paralysis is desired.

The reason cases are recorded where the paralysis is incomplete or unsuccessful is probably due to the fact that a certain method is used as a routine, being done in many instances by an assistant and at the expiration of the usual time the operation is begun. Some surgeons even begin the operation directly the injections have been made, which is obviously wrong.

If the injections are properly placed so that infiltration takes place around all the branches supplying the orbicularis, complete paralysis will be quickly and surely obtained.

Pressure over the site of infiltration seems to accelerate the action of the novocain. A cup of coffee before the operation is neither considered necessary nor always advisable, still patients who have been operated with and without coffee express their preference for the coffee.

To be able to eliminate the phrase "don't squeeze" from one's vocabulary during cataract extraction and to know that the patient cannot squeeze is a wonderful relief to the operator as well as greatly increasing the percentage of successful operations with good vision.

The second measure to be considered is the suturing of the wound.

Various methods have been advanced by operators from nearly every quarter of the globe, and these different methods have been reviewed from time to time in the literature, so to avoid repetition and as a review here seems rather unnecessary, it will be omitted.

Again the object is to support the principle rather than to advance a new way of closing the wound with sutures.

The fact that so many operators have advanced different methods of suturing the wound indicates first, the desire to be able to close the wound quickly and securely, and second, a difference in the personal equation of the operators.

That a conjunctival flap covering as much of the wound as possible is desirable seems to be generally admitted, and although conjunctival sutures are said not to hold the wound so firmly closed as the corneo-scleral suture, still they can be tight enough to wrinkle the cornea, which, of course, is too tight, and they will hold the wound firmly for a day or two which is usually sufficient.

Whether the suture or sutures are introduced before or after the section, has given rise to some controversy, there being good reasons on both sides, but paralyzing the musculature of the lids seems to eliminate many of the objections to introducing the suture after the section, except where corneal or scleral sutures are used. These,

of course, should be introduced before the section

The objection to the Kalt (9) suture is that the wound is not covered by a conjunctival flap

A modification by Verhoeff (10) of the Kalt suture, and later a modification of this, indicates his desire for a larger conjunctival flap

To complete the section with a large conjunctival flap before introducing the sutures has the advantage of being easily and quickly done and with very little trauma. Then, provided the lid musculature has been paralyzed, little difficulty is experienced in introducing one central suture, the loops of which can be placed to either side out of the way, and the cataract extracted, the suture tied and two more introduced. With sutures placed nasally and temporally, if a good bite of the conjunctiva is taken, the wound at both angles can be closed very tightly at locations where iris prolapse are most likely to occur following combined extractions. The removal of the sutures need not cause uneasiness. If 00 silk is used they very often come out themselves by the 4th or 5th day and if not the irritation from such small sutures is slight, but they can be removed very easily and safely if just scissors without forceps are used, as suggested by Ziegler. This method of suturing the wound has proved to be the most satisfactory for me in the average case, but when the cataract is dislocated or subluxated, I prefer having the flap prepared and the suture in place before making the section.

With Berens' (11) untied suture, some raise the objection that the loops of the suture get in the way during the extraction of the cataract, but there need be only two, one on either side, and if the silk is wet they will lie flat and out of the way. Certainly the advantages greatly counterbalance the objections.

If some method of suturing is used where the suture is introduced before the cataract is extracted, the advantage of being able at any time to close the wound quickly and easily are so evident and so outweigh the disadvantages, that to consider them separately seems unnecessary. A needle holder without a catch adds greatly to the safety and ease with which sutures can be introduced, also a very fine sharp corneal needle, 14 mm long, with an easy curve makes the introduction much easier.

The forceps tying of sutures simplifies and facilitates the procedure, as well as being an added protection against infection.

A very simple way to tie with forceps is to grasp the lower end of the suture with tissue forceps held in the left hand, a turn of the suture is made around the end of the needle holder which is held in the right hand and the upper end of the suture is grasped with the needle holder and drawn through the loop made by taking this turn. The first of the tie is in this way made and the loops of the suture placed to either side out of the way. When the wound is closed and the first tie is drawn tight, a second one is made in the

same manner. In completing the knot, it is desirable to use tissue forceps instead of the needle holder. The fine 00 silk used in suturing often slips through ordinary tissue forceps unless the silk is grasped at right angles to the serrations on the tips of the forceps. This is most unsatisfactory and annoying but if tissue forceps, with a groove on one arm of the biting surface of the forceps and a ridge on the other arm that fits into the groove, are used, the finest silk may be grasped at any angle and will not slip.

# CONGENITAL CYSTS OF THE KIDNEYS—TWO CASE REPORTS

## CASE NUMBER ONE

By EDWARD P. WARD, M.D., FLUSHING, N. Y.

(From a study made at the Philadelphia General Hospital)

**T**HIS paper was prompted by the occurrence of a case of polycystic kidneys, one of which was removed surgically, followed by no untoward complications nor sequelæ.

The case is that of a girl, twenty-one years of age, a nurse by occupation, who, until the onset of the attack which caused surgical interference, had an uneventful medical history with the exception of an uncomplicated attack of scarlet fever, four months previously.

Suddenly in the middle of the night she had colicky pains in the left lumbar region, which radiated down the left thigh and to the left shoulder, but were not severe enough to incapacitate her. She continued on duty until 7 A. M. the following morning, when she noticed a swelling to the left of the umbilicus, and was admitted to the infirmary. Physical examination disclosed the tumor, tenderness, rigidity and muscle spasm over left abdomen, without vomiting. Pulse and respirations were moderately accelerated. A differential white cell count showed fifteen thousand white blood cells seventy-eight percent of which were polymorphonucleurs.

Urine examination showed a slight trace of albumen and red blood cells. An acute surgical condition of the abdomen was suspected, an exploratory laparotomy was advised and done. A retroperitoneal tumor was found, which upon examination was discovered to be a polycystic kidney with a hemorrhage at its lower pole. The kidney on the opposite side was found to be polycystic also, but on account of the bleeding it was deemed advisable to do a nephrectomy.

FIG 1—Kidney removed at operation, showing gross characteristics and ruptured area with hemorrhage at lower pole

FIG 2—Section of polycystic kidney, demonstrating great number of cysts and apparently no normal kidney structure

The patient had an uneventful recovery, except for a mild cystitis and some abdominal pain.

Her fluid intake was limited and she excreted without difficulty over a liter of urine in twenty-four hours. Many chemical examinations of her blood disclosed no nitrogen retention exceeding twenty-six mmg of urea nitrogen per 100 cc. Uric acid nitrogen was a little increased but within normal limits as were the blood chlorides.

The two hours phenolsulphonephthalein output was but twenty-three per cent, but the patient felt well and wished to be discharged, which was granted, under the care of her physician. And she was, ten months later, living and apparently well.

This case is important from several view points. It shows the large "factor of safety" of the kidneys. It demonstrates that these polycystic kidneys may successfully "compensate" in face of an acute infection with notorious renal affinity.

In our efforts to study the occurrence of this condition as found at autopsies performed at the Philadelphia General Hospital since 1867, many records of cystic conditions of the kidneys were perused. As the cases accumulated, and were reviewed in panorama, they seemed to fall spontaneously into the following classes:

FIG. 3—Photomicrograph of polycystic kidney showing part of a greatly distended capsule, lined with markedly flattened cells, and projecting into the interior of the cyst, a compressed glomerulus

Either one of these may occur either as monocystic or polycystic forms

But as we are particularly interested in the congenital forms, they alone shall be discussed

(1) *Congenital Polycystic Form*—In the records of over 14,000 autopsies done at the Philadelphia General Hospital, during the last half century, by many noted pathologists there are but forty undoubted cases of congenital polycystic kidneys described. It was upon the diagnoses and description of those pathologists that we depended for our material. It may be of interest to know that in 1888 Sir William Osler made the first clinical diagnoses of this condition, confirmed by autopsy in our series, whereas up to 1909 there were but eight such cases diagnosed clinically, in the literature.

As undoubtedly everyone is now acquainted with this much pictured condition we will not take up time describing it, and will only say that occasionally a case is found in which the kidneys de-

part from the usual size and appear as small organs. Two such cases have been reported by Greene<sup>6</sup> and by Smith<sup>18</sup> in which the kidneys did not weigh over seventeen grams, and in one case only seven.

Microscopically, Ritchie<sup>15</sup> and also Meader<sup>14</sup> show that the cysts in many instances consist of dilated capsules, some of which contained compressed glomeruli, while in other instances, they are formed from dilated proximal tubules, either of the tubule itself or of its distal end.

We have been able to confirm these findings, and in addition have noted in sections of the polycystic and monocystic kidneys, cords of cells, having embryonal characteristics, which may represent non-canalized, vestigial tubules. We therefore infer that not only may there be a failure of union in embryonal life of the excreting and collecting portions of the kidneys, but also the cystic dilatation of the capsule may result from failure of the tubules to hollow out as well.

*Etiology*—As the etiology of this condition is after much investigation still undecided only a brief summary of this phase shall be given with reference to Moschowitz<sup>13</sup> for a more complete resume.

There is an undoubted familiar occurrence of this condition, upon which the reports of Wobus<sup>9</sup> and Crawford<sup>4</sup> are the most convincing.

The "Intra-uterine Inflammatory" theory of Virchow is not accepted today. This theory was followed by the "Multilocular Cysadenoma" theory of Brigid and Severi. Later the "Malformation Theory" appeared and was advocated in different forms by Von Mutach, Shattack and Hildebrand.

Ritchie<sup>15</sup> believes that the large cystic kidneys of adults differ from those occurring in children and resemble the cysts of the breasts that have a nervous origin. He also contends that the presence of concomitant cysts of the liver (and pancreas) which do not have a metanephros nor a

FIG. 4—Section of polycystic kidney showing cords of cells, which may represent non-canalized vestigial tubules.

mesonephros is against Shattack's admixture theory and declares in such cases the cause must be sought in the hypoblast. The occurrence of a case reported by Smith<sup>13</sup> in which there were over ten concomitant developmental anomalies, many of which were outside the genito-urinary system, lends weight to the assertion. Hinman and Morrison<sup>8</sup> have shown by stereoscopic X-ray examination after injection with barium sulphate and gelatin that the circulation in these organs simulates the fetal type.

Kampmeir<sup>9</sup> has shown that in a certain stage of development of the kidneys the tubules are cystic, a normal condition which may persist, the cysts continuing to grow, forming a monocystic or polycystic organ. The consensus of opinion of most investigators is that the condition is one form or other of a congenital aberrancy.

**Age at Death**—The average age at death in our series was forty-eight years, the youngest patient was one month of age, with exception of a fetus of four months.

FIG 5—A higher-power view of Fig 4

The oldest was eighty-four years. The largest number of cases occurred between the ages of forty and seventy years.

The most frequent causes of death were those associated with arteriosclerosis. Six patients died of an acute infectious disease, and five from chronic pulmonary affections, four of which were tuberculosis.

**Sex**—Females and males were practically equally affected. Of the forty cases twenty-one of them were in males and nineteen were in females.

**Race**—The white race seems strongly susceptible, as there were records of but three cases in the colored. This is contrary to opinion of N D

C Lewis<sup>11</sup> who believes they occur more frequently among the lower races of mankind, i.e., negroes. We have found but one case occurring in the insane and that was in a cretin.

**Involvement**—The condition was bilateral in 30 out of 40 cases but this percentage is influenced by the fact that in four cases there was but one kidney, the opposite one being atrophic. Of the

FIG 6—Section of four months' old fetal kidney showing multiple cysts

unilateral involvements, the left kidney was affected more than four times as often as the right.

**Concomitant Malformations**—In thirty-four cases, there were records of concomitant anomalies of development, but we feel that in practically every case, if a careful search is made other anomalies can be found. These anomalies varied in location and kinds. In six cases the liver also presented cysts a lower percentage than those found by other observers but higher than that of Johnson<sup>10</sup>. In four cases the pancreas also showed cysts. The other concurrent anomalies with the exception of a persistent urachus and a hydatid of Morgagni were confined in one manner or other to the kidneys and conducting system manifested in fetal lobulations, anomalous circulation, double or dilated ureters, absent kidney of opposite side and adenomas. Our results are closely allied to those of Ritchie's, with the exception of a lesser percentage of cystic livers, presence of cysts of the pancreas, and disproportionate race occurrence.

**Cystic Contents**—The content of the cysts is of interest. In our series, in most cases it was a yellow serous fluid and in a few cases contained uric acid, colloid material, calcareous matter or hemorrhage.

Many writers have described the fluid content of these cysts as urinous, or as modified urine, others say it is not urine, still others say it contains a small amount of urea.<sup>12</sup> In a few of the recent cases in which chemical studies were made the cyst fluid was found to resemble blood serum, being altered in composition when the blood serum showed similar changes.

For instance, in a case in which the patient showed uremic symptoms before death and at autopsy had bilateral cystic kidneys and cystic pancreas, a chemical examination of the cystic fluid, by Dr W G Karr, showed the following

Urea Nitrogen	85 mmg.	Per 100 cc. of Fluid
Uric Acid N.	7.8 mmg	Per 100 cc. of Fluid
Sugar	150 mmg	Per 100 cc. of Fluid
Chlorides	760 mmg	Per 100 cc. of Fluid

This analysis corresponds to that of the blood of a patient dying of uremia, and does not in any way resemble urine unless it may have undergone the "Serous Modification of Virchow"

Another case was that of a patient two years of age presenting a large tumor in the left abdomen. A paracentesis was performed and the fluid analyzed and contained

Urea N	15 mmg	Per 100 cc
Uric Acid	36	
Sugar	43 (Glycolysis)	
Total Protein	4.5%	

Later an exploratory laparotomy disclosed a polycystic kidney. We have done several more parallel examinations of blood and cystic fluids especially in the monocystic form and the relation between the blood and the cystic fluid has been the same.

Recently, Singer and Brams<sup>18</sup> reported the results of a clinical examination of the fluid of a polycystic kidney, but failed to note its relation to that of the blood.

(2) *Congenital Monocystic Form*—The monocystic form of these congenital aberrancies of the kidneys is not so spectacular as the polycystic, and consequently has not received as much attention from writers. Clinically, it is not important. Seldom diagnosed before autopsy and in no way interferes with a healthy existence.

The records of 14,000 odd autopsies produced but ninety-five undoubted cases of this anomaly.

*Etiology*—It is considered congenital and not inflammatory.

(1) Because of the hypersusceptibility of the kidney to congenital aberrancies, arising as it does from three separate complex, embryonal structures that are incorporated in the fully developed organ.<sup>2</sup>

(2) Because of the existence of a stage in the developing kidney, in which the tubules are normally cystic, which cystic form may persist.<sup>3</sup>

(3) The relatively rare occurrence of this condition and the prevalence of kidney inflammations.

(4) The great number of unilateral involvements.

(5) The great size of the cysts. The composition of the cystic fluid and structure of the cysts' walls.<sup>4</sup>

(6) Experimentally a papillitis with obstruction is followed by atrophy and not by cysts.<sup>5</sup> But against the congenital theory of origin is the relative absence of concomitant congenital anomalies as found in the polycystic form. In the ninety-five cases of our series there were but nine associated maldevelopments, four of which consisted of retained fetal lobulations, two anom-

alies of the colon, and the remaining three comprised of double ureters, anomalous renal arteries and a concomitant cyst of the adrenal.

The origin of the cysts is by no means a settled matter. The retention theory has many adherents, as have the new-formation and congenital theories, though the preponderance of evidence is in favor of the latter.

*Size*—The cysts varied in size from that of a "walnut," to that of a one 20 in diameter.

Four were multilocular and eight had associated one or more small cysts, which we inferred were due to a complicating chronic interstitial nephritis, and not of the same etiology.

*Position*—The process was unilateral in seventy-seven cases, or about eighty-one per cent. Of these the left side was involved in forty-two or fifty-four and five-tenths per cent. The upper pole was place of predilection in twenty-two out of the thirty positions recorded. Harpster<sup>7</sup> in his series of 95 cases of voluminous solitary cysts of the kidneys found that the majority were on upper pole and on the right side, as did Terrier<sup>9</sup>.

*Contents*—The cyst content in seventy-two cases was fluid. The remaining cases had cysts containing calcareous matter, hemorrhage, colloid, and infected material.

A chemical examination of the cystic fluid of the recent cases was made and the findings compared with those of the blood examined before death. They have a marked similarity, which made us conclude that whatever its origin the cyst fluid eventually was not urine, but body fluid, and chemically related, if not identical with, that of the blood plasma, being changed in composition with alterations in the blood.

TABLE NUMBER 1 SHOWING RELATION OF CYST FLUID, BLOOD AND NORMAL URINE

	Case	Urea	N Ur Acid	Sugar	Chlorides
Blood	M. N	63 mmg	6.4 mmg	164	
Cystic Fluid	M. N	65 mmg	6.4 mmg	190	
Blood	D. B	32 mmg	Not Det.	Not Det	
Cystic Fluid	D. B	40 mmg	4.4 mmg	130	660 mmg
Blood*	T. H	38 mmg	3.8 mmg	120	
Cystic Fluid	T. H	45 mmg	4.6 mmg	125	
Normal Urine		350 mmg	7.5 mmg	0	100-150 mmg

\* Examined one week before death.

Units are in mmg per 100 cc.

*Sex*—The occurrence in relation to sex showed the condition in our series to be more prevalent in males than in females, in a ratio almost five to two. Harpster<sup>7</sup> found a preponderance in females in the cases of large serous cysts of the kidneys, in the literature. It is probable therefore, that sex has little if any significance.

*Race*—The black race was affected in eight cases, or eight and four-tenths per cent. Of our series, this is somewhat less than our percentage of total autopsies on negroes.

*Cause of Death*—The cause of death in most

cases was that in which arteriosclerosis and its concomitant condition played a prominent part. Most of the patients died of chronic interstitial nephritis, chronic myocarditis, uremia or apoplexy. A minority died of pulmonary tuberculosis, malignancy and broncho-pneumonia, acute infectious diseases like typhoid fever, meningitis and acute endocarditis, while a few died of carbon monoxide poisoning, sunstroke and tracheal obstruction. None bore any relation to the cysts of the kidneys.

**Summary**—We report a case of bilateral polycystic kidneys, in which a nephrectomy was performed, the patient surviving and, ten months later, living and well.

A review of fourteen thousand autopsies at the Philadelphia General Hospital shows the conditions to be rare, the polycystic form occurring but forty times and the monocystic, ninety-five. Though Smalley<sup>17</sup> discovered four cases of polycystic kidneys in one year, Cunningham<sup>5</sup> found but thirty-four large serous cysts in over four thousand autopsies.

The polycystic form is almost always bilateral. The monocystic is more often unilateral. Both appear more often on the left side, when one side alone is involved, and the upper pole is the site of predilection in the monocystic.

In both conditions the white race shows a greater preponderance of cases.

Other associated anomalies can probably always be found if carefully looked for in the polycystic form, while they are uncommon in the monocystic form.

The fluid content of the cysts in both cases

chemically resembles body fluid, bearing a definite relation to the blood plasma and showing changes when it is altered.

Both are compatible with a normal life, even in the case of polycystic kidneys, when one is removed.

## CASE NUMBER TWO

By E. F. KENT, M.D., BROOKLYN, N. Y.

(From a study of a case made at the Kings County Hospital on the service of John W. Parrish, M.D.)

**R.** D. 7 years, born, U. S. A., parents, Swedish-Americans, admitted on 7-6-27, died 7-15-27.

**History**—The mother states that the child was prematurely born at the age of seven months and three weeks. The birth weight was less than five pounds. At birth he had a "liquid abdomen." Because of this instruments were used at the delivery. "A specialist placed a drop of salve over the kidney area to draw off the water." After about three weeks the abdomen became less distended, though it has always been very large.

The child did very poorly and was continually in questionable health and comfort. He has been observed in numerous hospitals and no definite relief or diagnosis given. The only encouragement was a request for autopsy.

At the age of two and one-half years he was

in an auto accident. He suffered "internal injuries" and was ill for about four months. At this time cystoscopic examinations showed pus and blood from one kidney, which one not recalled. From then on the child seemed more prone to be ill. There were periods of comparative alleviation.

About one year ago he had a very severe hemorrhage from the nose and mouth. He has had several of these since then. About three weeks before admission to Kings County Hospital the last one occurred. This was unusually severe and the mother believes that it filled a basin to the halfway mark.

About two years ago a hernia repair was done under local anesthesia because the child was pronounced as tuberculous by the family physician.

The boy appears to be very intelligent. He

states that he has been ill for two weeks because of a bad cough which made it hard for him to breathe.

The father of the patient died two years ago of pulmonary tuberculosis. He was ill for years. The family history is otherwise unessential.

### PHYSICAL EXAMINATION

*General*—Male, seven years old, orthopneic, anaemic, slightly cyanotic, though not in proportion to the orthopnea, malnourished, well-oriented in all spheres, and evidently acutely and chronically ill.

Fig. 7—Thickened bladder, distended ureters, and cystic kidneys (the right one split open) from case two

*Head*—Lips, conjunctiva and ears show marked anaemia. The superficial facial veins are prominent. The ears are clear. The pupils react to light and accommodation, consensual reflexes present, ocular movements good. The nares are normal in appearance, though show an anaemic blanch to the mucous membrane. The tonsils are hypertrophied and cryptic. There are palpable lymph nodes at the angle of right mandible.

*Thorax and Lungs*—Accessory muscles of respiration in use, pronounced clavicular fossæ and diaphragmatic retractions. Slight rachitic rosary. Increased dullness, diminished breath sounds and coarse rales at the right base, scattered moist rales throughout. The lungs give the impression of a pulmonary congestion due to cardiac decompensation.

*Cardiac*—Marked increased cardiac dullness. The apex is in the sixth intercostal space and outside the nipple line. Tone is good, systole prolonged, and slight systolic murmur at the apex. Pronounced carotid pulsations present.

*Abdomen*—Marked symmetrical distension. On palpation a definite mass rises from the pelvis and extends two fingers' breadth over the umbilicus,

much like the pregnant uterus. This is probably distended bladder, though it feels like a uterine fibroid. The liver edge is palpable for three fingers below the costal margin. There is a palpable mass on the right side and below the liver. It is apparently not attached to the liver and is non-tender. This gives the impression of hypernephroma or cystic Meckles diverticulum. There is no definite abdominal tenderness on moderately heavy palpation.

*Genitalia*—Show evidences of old circumcision and hernia repair.

*Rectal*—Indefinite mass in bladder region and extending up.

*Extremities*—No deformity. Tendon reflexes increased.

*Blood Pressure*—150/140.

*Impression*—Retention of urine, hypernephroma, and cardiac decompensation.

### NOTES

The patient was catheterized at various times and amounts from thirty-two ounces and less were obtained. This despite the fact that the child had fairly regular voidings of from two to eight ounces of urine. The bladder was never smaller than midway to the umbilicus.

The boy became more fretful, the abdomen tender, and examinations less satisfactory as time passed. The mass in the right abdomen was palpable only at times. The lungs cleared under medication until the terminus. The patient became clinically more and more uræmic. Some blood was given subcutaneously. Preparations were under way for a direct donor, the mother did not match. The child was too weak for cystoscopy or any surgical procedure.

Consultations gave no definite opinions, though the speculations included perinephritic abscess, congenital polycystic kidneys, hypernephroma, congenital spasms of bladder sphincters, hydrourters, diverticulum, and abdominal neoplasm.

The X-rays were negative. R.B.C., 2,560,000, WBC, 9,400, Polys, 59 per cent. The urine showed sp. gr. 1006 to 1010, otherwise negative. The temperature varied from 98.6 F to 104 and septic in type. The pulse followed the temperature fairly well.

The child steadily lost ground and died.

*Clinical Diagnosis*—Retention of urine, acute and chronic, atony of bladder, chronic cystitis, hydronephrosis, chronic nephritis, interstitial, chronic myocarditis, chronic uræmia, simple anaemia.

### Autopsy—

*Anatomical Findings*—Hydronephrosis, pyelonephritis, chronic cystitis, chronic myocarditis. The body is that of an anemic white male child.

cases was that in which arteriosclerosis and its concomitant condition played a prominent part. Most of the patients died of chronic interstitial nephritis, chronic myocarditis, uremia or apoplexy. A minority died of pulmonary tuberculosis, malignancy and broncho-pneumonia, acute infectious diseases like typhoid fever, meningitis and acute endocarditis, while a few died of carbon monoxide poisoning, sunstroke and tracheal obstruction. None bore any relation to the cysts of the kidneys.

**Summary**—We report a case of bilateral polycystic kidneys, in which a nephrectomy was performed, the patient surviving and, ten months later, living and well.

A review of fourteen thousand autopsies at the Philadelphia General Hospital shows the conditions to be rare, the polycystic form occurring but forty times and the monocystic, ninety-five. Though Smalley<sup>17</sup> discovered four cases of polycystic kidneys in one year, Cunningham<sup>5</sup> found but thirty-four large serouscysts in over four thousand autopsies.

The polycystic form is almost always bilateral. The monocystic is more often unilateral. Both appear more often on the left side, when one side alone is involved, and the upper pole is the site of predilection in the monocystic.

In both conditions the white race shows a greater preponderance of cases.

Other associated anomalies can probably always be found if carefully looked for in the polycystic form, while they are uncommon in the monocystic form.

The fluid content of the cysts in both cases

chemically resembles body fluid, bearing a definite relation to the blood plasma and showing changes when it is altered.

Both are compatible with a normal life, even in the case of polycystic kidneys, when one is removed.

## CASE NUMBER TWO

By E. F. KENT, M.D., BROOKLYN, N. Y.

(From a study of a case made at the Kings County Hospital on the service of John W. Parrish, M.D.)

**R.** D. 7 years, born, U. S. A., parents, Swedish-Americans, admitted on 7-6-27, died 7-15-27.

**History**—The mother states that the child was prematurely born at the age of seven months and three weeks. The birth weight was less than five pounds. At birth he had a "liquid abdomen." Because of this instruments were used at the delivery. "A specialist placed a drop of salve over the kidney area to draw off the water." After about three weeks the abdomen became less distended, though it has always been very large.

The child did very poorly and was continually in questionable health and comfort. He has been observed in numerous hospitals and no definite relief or diagnosis given. The only encouragement was a request for autopsy.

At the age of two and one-half years he was

in an auto accident. He suffered "internal injuries" and was ill for about four months. At this time cystoscopic examinations showed pus and blood from one kidney, which one not recalled. From then on the child seemed more prone to be ill. There were periods of comparative alleviation.

About one year ago he had a very severe hemorrhage from the nose and mouth. He has had several of these since then. About three weeks before admission to Kings County Hospital the last one occurred. This was unusually severe and the mother believes that it filled a basin to the halfway mark.

About two years ago a hernia repair was done under local anesthesia because the child was pronounced as tuberculous by the family physician. The boy appears to be very intelligent. He

states that he has been ill for two weeks because of a bad cough which made it hard for him to breathe.

The father of the patient died two years ago of pulmonary tuberculosis. He was ill for years. The family history is otherwise unessential.

#### PHYSICAL EXAMINATION

*General*—Male, seven years old, orthopneic, anaemic, slightly cyanotic, though not in proportion to the orthopnea, malnourished, well-oriented in all spheres, and evidently acutely and chronically ill.

FIG. 7—Thickened bladder, distended ureters, and cystic kidneys (the right one split open) from case two.

*Head*—Lips, conjunctiva and ears show marked anaemia. The superficial facial veins are prominent. The ears are clear. The pupils react to light and accommodation, consensual reflexes present, ocular movements good. The nares are normal in appearance, though show an anaemic blanch to the mucous membrane. The tonsils are hypertrophied and cryptic. There are palpable lymph nodes at the angle of right mandible.

*Thorax and Lungs*—Accessory muscles of respiration in use, pronounced clavicular fossae and diaphragmatic retractions. Slight rachitic rosary. Increased dullness, diminished breath sounds and coarse rales at the right base; scattered moist rales throughout. The lungs give the impression of a pulmonary congestion due to cardiac decompensation.

*Cardiac*—Marked increased cardiac dullness. The apex is in the sixth intercostal space and outside the nipple line. Tone is good, systole prolonged, and slight systolic murmur at the apex. Pronounced carotid pulsations present.

*Abdomen*—Marked symmetrical distension. On palpation a definite mass rises from the pelvis and extends two fingers' breadth over the umbili-

cus, much like the pregnant uterus. This is probably distended bladder, though it feels like a uterine fibroid. The liver edge is palpable for three fingers below the costal margin. There is a palpable mass on the right side and below the liver. It is apparently not attached to the liver and is non-tender. This gives the impression of hypernephroma or cystic Meckles diverticulum. There is no definite abdominal tenderness on moderately heavy palpation.

*Genitalia*—Show evidences of old circumcision and hernia repair.

*Rectal*—Indefinite mass in bladder region and extending up.

*Extremities*—No deformity. Tendon reflexes increased.

*Blood Pressure*—150/140.

*Impression*—Retention of urine, hypernephroma, and cardiac decompensation.

#### NOTES

The patient was catheterized at various times and amounts from thirty-two ounces and less were obtained. Thus despite the fact that the child had fairly regular voidings of from two to eight ounces of urine. The bladder was never smaller than midway to the umbilicus.

The boy became more fretful, the abdomen tender, and examinations less satisfactory as time passed. The mass in the right abdomen was palpable only at times. The lungs cleared under medication until the terminus. The patient became clinically more and more uremic. Some blood was given subcutaneously. Preparations were under way for a direct donor, the mother did not match. The child was too weak for cystoscopy or any surgical procedure.

Consultations gave no definite opinions, though the speculations included perinephritic abscess, congenital polycystic kidneys, hypernephroma, congenital spasms of bladder sphincters, hydrourters, diverticulum, and abdominal neoplasm.

The X-rays were negative. R.B.C., 2,560,000; WBC, 9,400, Polys, 59 per cent. The urine showed sp gr 1006 to 1010, otherwise negative. The temperature varied from 98.6 F to 104 and septic in type. The pulse followed the temperature fairly well.

The child steadily lost ground and died.

*Clinical Diagnosis*—Retention of urine, acute and chronic, atony of bladder, chronic cystitis, hydronephrosis, chronic nephritis, interstitial, chronic myocarditis, chronic uremia; simple anaemia.

#### Autopsy—

*Anatomical Findings*—Hydronephrosis, pyelonephritis, chronic cystitis, chronic myocarditis. The body is that of an anemic white male child.

about seven years old, post-mortem rigor and lividity not present; moderate degree of emaciation, hair, white, face, swollen, no evidence of trauma externally

Median incision made from suprasternal notch to symphysis and the sternum removed

*Lungs*—Not adherent, normal size, pale anemic color, on section, tissue normal except for pallor and somewhat edematous condition

*Heart*—Approximately twice normal size, left heart dilated and markedly hypertrophied, myocardium, pale, valves and aorta, normal, coronaries, patent and elastic

*Liver*—Normal shape, pale color, parenchyma paler than normally, tissue edematous

*Spleen*—Twice normal size, firm, excess fibrous tissue

*Kidneys, Ureters, Bladder*—Removed en masse Kidney, twice normal size and composed practically entirely of cysts, little normal kidney substance remains Cysts contain thick, yellowish, pus-like material Ureters dilated to calibre of about one inch and are coiled on themselves They are filled with a pus-like material Bladder wall markedly hypertrophied and sections with extreme resistance, the cavity contains about one half ounce of the similar material

*Stomach, Intestines, Pancreas*—Apparently natural

*Mesentery*—Contains numerous small, soft, noncaseous nodes

*Thymus*—Slightly enlarged, soft and edematous

Cause of death—chronic myocarditis, pyelonephritis

#### HISTOLOGICAL DATA

*Heart*—Parenchymatous myocarditis

*Lungs*—Moderate chronic passive congestion, areas of focal atelectasis and emphysema

*Liver*—Cloudy swelling, edema

*Spleen*—Congestion, edema

*Pancreas*—Normal

*Testicle, Epididymis*—Normal

*Mesentery Lymph Node*—Hyperplastic lymphadenitis

Note—The kidneys were not sectioned, reserved for museum purposes

Pathological Specimen.—The hydronephrosis shows up well in the hypertrophied bladder, ureters and in the continuity of the pelvis of the kidneys with the apparent cystic formations in kidneys

## FIRST YEAR OF THE MEDICAL PRACTICE ACT\*

By HAROLD RYPINS, M.D.,

Secretary, New York State Board of Medical Examiners, Albany, N. Y.

**A**LTHOUGH the so-called Webb-Loomis bill became a law by the signature of Governor Smith on May 17, 1926, it was not until the fall of that same year that the administrative machinery necessary for making the act effective was organized, so that for practical purposes the law has been in effect approximately one year. At this time it is proper that we should take stock of the results of this important legislation and that we should give our results to the general public and to the medical profession. To do this in an intelligent manner requires taking into consideration two factors—firstly, the objects of this proposed modification of the Medical Practice Act, and secondly, the establishment of some acceptable criteria for measuring the effectiveness of this legislation.

In general the objects of the proponents of this legislation may be briefly classified as follows:

- I To drive out illegal quacks and charlatans
- II To create a Grievance Committee
  - (a) To discipline licensed physicians
  - (b) To dispose of complaints against

- III To establish and regulate the profession of physiotherapy
- IV To set up permanent administrative machinery for the enforcement of the law
  - (a) To compile an annual, accurate registry of physicians
  - (b) To raise sufficient funds for the proper administration of the act

With the lapse of one year we should now ask ourselves whether or not these four major purposes have been accomplished and what measure of success has been reached in the first year's administration of the law.

Before proceeding to an analysis of these factors I wish to state that a year's intimate association with this matter has satisfied the Department of Education, upon which the burden of this administration largely falls, that the act is doing at least as much, if not more, than was expected of it. It will be recalled that the Department went on record as stating that there were approximately 16,000 licensed and 4,000 unlicensed practitioners in this State, so that

\* Read before the Society of Medical Jurisprudence, December 12, 1927

an unguided patient had one chance in five of falling into the hands of a quack or charlatan. Our registration figures now show that our estimate of the number of licensed physicians was too low, the total approaching approximately 18,000, but our experience leads us to believe that our estimate of the illegal practitioners was not too high and that 4,000 was probably a conservative estimate of the number of illegal practitioners in New York State. The Department stated that it would take three or four years to sweep the State reasonably clean of medical quacks and charlatans but that probably upwards of 1,000 could be eliminated during the first year. As will be seen later, this figure was a very accurate estimation of what could actually be accomplished in one year but there is reason to believe that the number of quacks and charlatans will diminish more rapidly in the next few years, although there will never be a time when some quacks will not be settling in the State.

The value of a Grievance Committee and the establishment and regulation of the profession of physiotherapy were considered as secondary factors and no definite prognosis was made concerning their effectiveness. To reiterate then, up to the present time the first year's administration of the Medical Practice Act has more than satisfied those charged with its administration that it has accomplished approximately what was anticipated and that more illegal practitioners of medicine have been eliminated in the last year than in the two decades preceding this modification of the law.

#### ELIMINATION OF ILLEGAL PRACTITIONERS

In estimating the number of illegal practitioners that have been driven out of the State it is naturally impossible to give statistical figures but there are certain criteria which lead me to feel fully warranted in the assertion that not less than 1,000 quacks and possibly more have discontinued practicing in New York State during the past year. This very satisfactory estimate is arrived at on the basis of a number of criteria. For example, a close check-up on the illegal practitioners of Buffalo shows that 50 known illegal practitioners can no longer be located in Buffalo. If Buffalo may be taken as a fair sample of the State, the proportion of 50 600,000  $\times$  11,000,000, gives the figure of illegal practitioners eliminated from practice as 1,100. Again, the district attorney of Kings County investigated 35 cases. Of these 35 cases, 6 were convicted, 3 cases were dismissed, 2 are pending before the magistrate and 6 are pending in Special Sessions, while of the remaining 18, not one can at present be located in Brooklyn. In other words of 35 cases investigated in Kings County, 24 have been found guilty or have disappeared from practice and 8 are now under arrest. The number of illegal practitioners in Kings County has never

been estimated but from a sample of 35 cases investigated, only 3 are now known to be practicing.

Again, my inspectors, who are specially trained in securing evidence of illegal practice, even where there is no sign displayed, report to me that in the City of New York it is now almost impossible to secure treatment by an illegal practitioner although they state that many of them are still operating under cover in constant fear of treating police agents.

Officers of the states of Pennsylvania, New Jersey and Canadian provinces have complained bitterly of the number of cases of quacks who have crossed over the New York boundaries to operate in these neighboring territories.

Lastly, the unauthorized use of the title "Dr." either by signs or on advertising literature has practically discontinued. This is very important as it shows the prospective patient at least that he is taking treatment from one who is not a licensed physician and therefore at his own risk.

As I previously stated these data would appear to make the estimate of 1,000 illegal practitioners who have been driven out of New York State in the past year conservative and justifiable.

#### PROSECUTIONS

It might appear natural to estimate the number of illegal practitioners eliminated by the actual number of prosecutions and convictions but this is certainly not the case.

Cases arrested	103
Convictions	30
Acquittals and dismissals	14
Arrested and pending trial	58
Died before trial	1

Naturally these defendants have resorted to the usual law's delays but our experience shows that about two-thirds of those arrested are held and finally convicted, so that it seems fair to estimate that of the 103 cases arrested during the past year approximately 65 will be convicted. When it is seen that out of 728 cases investigated only 103 have been arrested it is obvious that each arrest probably means that 5 other individuals have been frightened from practice and that for every conviction, particularly with jail sentences, probably 20 illegal practitioners have discontinued their practice. No one of these methods is a scientific one for statistical estimations, but putting them altogether I believe they indicate that not less than 1,000 illegal practitioners have left the State during the past year.

#### CONVICTIONS AND SENTENCES

Experience has shown that if after arrest an illegal practitioner is held by the magistrate the chances for conviction are well over 50%. The statute provides for a fine of not more than \$500.00 or more than one year imprisonment or

both, but in general the courts of special sessions have strongly preferred giving jail sentences as they feel that this is the shortest way to eliminate illegal practitioners from the State. Four cases have received one year jail sentences, several have received 90 days and most of the others 30 days, in which case the operation of the sentence is often suspended provided the individual discontinues the illegal practice. A few fines, ranging from \$25.00 to \$500.00 have been imposed. Although jail sentences for more than 30 days appear somewhat severe there is no doubt that they act as a strong deterrent and doubtless the experience of the magistrates in similar cases justifies these severe penalties.

#### TYPE OF PRACTITIONERS PROSECUTED

Curiously enough there is no one special group of illegal practitioners found either on investigation or by classification of arrests. They are widely distributed among chiropractors, naturopaths, physicians without licenses, faith healers, druggists, laymen, herb doctors, naprapaths, bone setters, and licensed practitioners in the lesser allied fields of optometry and chiropody.

#### DISTRIBUTION IN STATE

It is obvious that the Medical Practice Act has been most efficacious in Greater New York, over 85% of our cases being there. This can be explained by three factors—(1) cases in New York City are not tried by a jury but by three magistrates in a court of special sessions, (2) we have had the generous cooperation and assistance of the district attorneys of both New York and Kings Counties, and (3) the attorney-general's office has been consistently well equipped to handle these cases in New York City. In the up-state prosecutions on the other hand, we are in the first place faced with the bugbear of a jury trial where most of the jury are found to be friends or neighbors of the defendant and many of them are very enthusiastic about the success of various cultists. Until the present time, also, we have not had the full-time services of a deputy attorney-general to prosecute these cases up-state, but the Department has just appointed a new man who will devote his entire time to these cases and it is believed that due to this and the increasing efficiency of our inspectors, our efficiency in up-state prosecutions will improve.

In general, it may be said that the legal machinery, both theoretical and practical, for investigating cases of illegal practice is thoroughly satisfactory and that the creation of a special office for handling these matters is the only effectual way of dealing with them.

#### GRIEVANCE COMMITTEE

The Grievance Committee was appointed for

two reasons—first, to investigate improper practice of licensed physicians and recommend the proper discipline to the Board of Regents, and second, to act as a filter for the numerous unfounded cases of malpractice and negligence claims that are yearly brought against practicing physicians. The Grievance Committee, under the chairmanship of Dr. Orrin Sage Wrightman, has worked out a very satisfactory manner of handling these cases and within a short time Dr. Wrightman's committee will publish a resume of their first year's accomplishments. Curiously enough what seemed to be the minor feature of the Grievance Committee has so far turned out to be the major one, as through the cooperation of its officers and this Department not less than 35 unfounded charges, looking to the discipline of practicing physicians have, upon investigation, been disposed of and so far as I know there is no single one of these cases that has ever reappeared in any civil court. In other words, a large number of individuals complaining against practicing physicians are willing to bring their complaints of malpractice or negligence to the Grievance Committee and are apparently well satisfied when after investigation the Grievance Committee reports that no basis for action on the part of the Committee exists in law. This is a procedure which, of course, saves expense on the part of the complainant as well as undue notoriety and expense on the part of the practicing physician, so that this particular function of the Grievance Committee alone has more than justified the cost of the annual registration imposed upon the profession. It may be considered as a type of insurance in which by paying an annual fee of two dollars, the chances of a physician's being brought into a court on a civil suit are eminently minimized.

#### PHYSIOTHERAPY

Up to the present time about 125 physiotherapists have been licensed to practice. It has been found that there is a very definite need on the part of the public and practicing physicians for this type of technical assistant and the number so far licensed is small enough so that their activities are fairly well under control. The law does not permit a licensed physiotherapist to give medicine nor to treat diseases except under the direction of a duly licensed physician, so that the former practice whereby these individuals engaged in diagnosing or treating unscientifically is very well under control.

Very fortunately New York University has started a four-year course in physical training and physiotherapy in association with the Hospital for the Ruptured and Crippled on a university standard and it is believed that the establishment of such a course in an organized university will practically drive all the competing commercial schools out of the field.

It is still difficult to estimate the real value of

the non-medical physiotherapists but up to the present time I believe that the creation of this profession, under proper management and control and with high educational standards, is of a great benefit to the community and to the medical profession

Perhaps the chief respect in which the present New York State statute is superior to the medical practice act in other states is that it has actually created a permanent administrative machinery for the sole purpose of enforcing the provisions of the statute. It has been said that the object of this legislation was to put teeth in the Medical Practice Act. Even more so, it was to create an organism which would intelligently and forcefully manipulate these teeth

The Medical Practice Act is administered by the Secretary of the State Board of Medical Examiners under the supervision of the First Assistant Commissioner of Education with the assistance of two full-term deputy attorneys-general, a bureau for the handling of annual registration, a force of from five to seven full-time inspectors and the necessary clerical help. To this should be added the very generous voluntary assistance of the various district attorneys, more particularly the assistant district attorney of New York County, Mr. Michael A. Ford and the assistant district attorney of Kings County, Mr. George F. Palmer, Jr., as well as the very valuable assistance given by the Health Department of the City of New York, through Dr. S. Dana Hubbard.

The funds for administering this office are derived from the approximately \$36,000.00 annual registration fees and are just about sufficient to carry on the work effectively.

#### NUMBER OF REGISTERED PHYSICIANS

After the admittedly indefinite figures prepared in all of the foregoing it is with pleasure that I believe I can report more accurately than anyone else the actual number of practicing physicians in New York State for the year 1927 and who are registered as actively engaged in practice.

Physicians	17,430
Osteopaths	331
Physiotherapists	120

This doubtless represents more than 95% of those actively engaged in practice.

The annual registration list has proven of great value to court officers, inspectors, health officers and others and judging by the number of requests for lists of the registered physicians received from the general public, it is also being used by the public in selecting the wheat from the chaff among physicians.

#### SUMMARY

An estimate of the result of the first year's operation of the Webb-Loomis bill justifies the conclusion that it has more than shown its value and has accomplished all that was predicted of it by its proponents.

I During the past year not less than 1,000 illegal practitioners of medicine have been eliminated from the State.

II The Grievance Committee has functioned successfully and very satisfactorily to the benefit of the medical profession.

III The establishment of the new profession of physiotherapy has justified itself.

IV It can be stated definitely that there are at least 17,430 licensed physicians, 331 licensed osteopaths and 120 licensed physiotherapists, registered as practicing in the State of New York for the year 1927.

V The legal and administrative machinery of the Medical Practice Act has proven highly satisfactory and is the one single feature of any medical practice act which determines success or failure.

Finally, the gratitude of the Department of Education is expressed for the hearty cooperation of the practicing physicians, the attorney-general's office, the offices of the various district attorneys and health departments, particularly in New York City, as well as the various judges throughout the State, in making this act successfully operative.

## SOME OF THE MORE COMMON LOWER ABDOMINAL CONDITIONS AND EMERGENCIES OCCURRING IN BOTH THE MALE AND THE FEMALE\*

By JOHN B. DEAVER, M.D., PHILADELPHIA, PA.

**A** DISCUSSION of some of the more common conditions and emergencies in the lower abdomen, will, I dare say, be more welcome to many of you than the much more frequently discussed diseases of the upper abdomen. Although I must confess to being a guilty party to the latter, I hope I have not sinned in vain. I trust what I shall say will be of interest to all of you, the general practitioner, the surgeon and the specialist.

The most common condition, of course, is appendicitis, but at this time it is a special type of that disease, and I may say one that often causes confusion—pelvic appendicitis. It is an accepted fact that in about one third of cases of appendicitis the appendix is in the pelvis and occupies a position immediately beneath the mesentery or the terminal ileum or immediately beneath the terminal ileum alone. It is then in the false pelvis, that is, above the ileocecal line. But when the appendix extends well down into the pelvis, that is, below the ileocecal line or lies wholly in the pelvis and is inflamed or perforated, the diagnosis is more often than not missed. This position of the diseased appendix has been responsible for numerous sins of omission and more of commission leading to fatalities because the condition is diagnosed as an inflammation of the uterine appendages, particularly of the right side, and diverticulitis of the sigmoid. During recent years, since diverticulitis of the sigmoid has come to be better understood than formerly, pelvic appendicitis has often been mistaken for it. This differentiation, however, is not by any means easy nor is it always possible. After the onset of pelvic peritonitis, and especially if it is already in an advanced stage, the diagnostic picture is much befogged, of which I shall speak presently. In the diagnosis of lower abdominal diseases examination per rectum should always be made, and if this is done gently with a refined touch much information can be gained. During the many years, and happy years they were, that I was privileged to teach topographical anatomy I always required my students to study carefully what was to be made out by vaginal and rectal examination of the cadaver. By gentle examination I mean carefully introducing the greased finger into the rectum without causing any discomfort or pain. This is done by asking the patient to bear down against the finger as it is being introduced into the rectum. The sphincter is thus dilated and the examination facilitated. This manipulation rarely fails to make a "hit" with patients, especially those who have

experienced the more painful examination by less gentle means. In this way also the confidence of the patient is acquired, the psychologic effect of which, as you all know, is most important.

I have referred to the presence of advanced peritonitis befogging the diagnosis. When peritonitis, if at all advanced, is present the history, plus the findings by examination per rectum and vaginam, is about all from which we can take our bearings. In such cases we are like the captain of a ship in a dense fog whose compass is out of commission and who has only his experience and what is to be learned from soundings to guide him. In pelvic appendicitis, particularly where the appendix is in the lower pelvis, the distinguishing points, in addition to the history, are left-sided pain, bilateral rigidity and vesical symptoms. So-called left-sided appendicitis is a misnomer. It occurs only where there is complete transposition of viscera. Personally, I have met with only one instance of this anomaly in the many thousand cases of appendicitis I have operated. This case was diagnosed pelvic appendicitis, and on opening the abdomen upon the right side, the sigmoid presented. I opened the left side and exposed the cecum and the appendix located in the pelvis. Introducing my hand into the upper abdomen I found the liver on the left and the spleen on the right side.

The initial pain in appendicitis, as is well known, is as a rule referred to the peri-umbilical or epigastric region and in a very short time is referred to the location of the appendix. Oftentimes, the case is at first considered a simple bellyache. If, however, it is a case of appendicitis, palpation will reveal tenderness over the appendix, although the pain may be referred elsewhere. In the early stage there is only appendiceal irritation or appendiceal colic. In an acute attack, occurring in a chronically diseased appendix, the initial pain is generally at once referred to the site of the appendix.

In this connection let me say a word with regard to the frequent contention that chronic appendicitis is not a clinical entity. With all due respect to those who hold this opinion, I am free to say that my experience convinces me that chronic appendicitis is as much a disease as ulcer of the duodenum or stomach, to which it is often related, in that the infection causing the ulcer often has its origin in the appendix. You all know Sir Berkeley Moynihan's well known dictum that most ulcers of the duodenum and stomach originate in the appendix. I have no doubt many of you here agree with him. I do not hesitate to repeat what I have frequently said. Before deciding upon a diagnosis in an abdominal ailment, think first, last, and always

\* Read before the Seventh District Branch Meeting at Geneva, N. Y., September 28, 1927.

of the appendix. In other words, in determining the condition causing an abdominal ailment we most often find it in the appendix. I like to speak of this troublesome little organ as our first love because of its former connection with the late Reginald Fitz who called attention to its ubiquitous rôle, and our continued love from the relation it still bears to obscure abdominal ailments. I admit that the removal of a chronically diseased appendix does not by any means always relieve abdominal symptoms. But this is no proof that chronic appendicitis does not exist as a disease, but may merely prove that an incomplete diagnosis has been made. Removal of a chronically diseased appendix will not correct symptoms caused by such conditions as mobile cecum, coloptosis or gastropptosis, chronic colitis, incipient tuberculosis of the cecum or of the mesenteric glands, especially the gland at the ileocecal junction, colonic stasis, carcinoma of the cecum, stone in the right ureter, etc. Nor will it cure a retroperitoneal lymphangitis with evident and palpable inguinal lymph glands, the cause for which, by the way, I have occasionally found to be a superficial infection of the toe or of the lower leg or carcinoma of the lower rectum or an incipient right inguinal hernia or an undescended testicle advancing along the inguinal canal attempting to find a final resting place. In the female this may also be due to a right ovary or a Fallopian tube trying to excursion into the inguinal or femoral canal or a small diverticulum of the small intestine playing hide and seek with the inguinal canal by way of the internal abdominal ring, where it finally becomes ensnared and strangulated and demands operation for the release of the strangulation. This is a pretty large bill of fare, is it not?

Practice in making a physical examination is of the greatest value. This should be done with the body exposed and not through the clothes. Our armamentarium is replete with much that is good, and much that is no good, but nevertheless it is our duty in this respect to give the patient the benefit of every known rational (with emphasis on the rational) procedure, by which one may arrive at a correct conclusion. And in this armamentarium I consider the physical examination with the trained touch of as much importance as any of the more or less useful adjuncts we have. With this somewhat lengthy, and I hope pardonable digression, let us return to our discussion.

A less common condition than pelvic appendicitis, but one which is demanding attention today, is diverticulitis of the sigmoid. This is met with clinically as one of three varieties—interstitial inflammation of the sigmoid, inflammation of a diverticulum of the sigmoid, and inflammation of the epiploic appendages of the sigmoid. The symptoms and signs of these varieties are more or less the same. Differentiation between them

is not always possible nor is it very important, as the line of treatment is practically the same, except in the perforative variety, in which the pain is very excruciating and tenderness very marked. These cases, unless seen very early before the onset of other than a local circumscribed peritonitis are not operative. Treatment should consist of anatomic and physiologic rest, that is, gastric lavage, the local application of cold, and enough morphia to relieve the pain and quiet the peristalsis. This line of conservative treatment is usually successful, while indiscriminate operation is attended by a high mortality. When a circumscribed collection of pus is formed, simple incision (extra-peritoneal approach, within most instances removal of the appendix) and drainage is the procedure indicated.

The history of diverticulitis is usually that of constipation, sheep-manure stools, much intestinal gas with inability to pass it freely enough to give comfort, associated with more or less marked lower left abdominal soreness or pain and tenderness to deep and firm pressure externally and by high rectal examination. In the presence of a tumor, in either sex, one must first determine whether the process is inflammatory or non-inflammatory. I need not call attention to the consideration of the pulse rate, the temperature and the blood picture. In a male, an inflammatory process may indicate psoriasis or psoriasis abscess, while in the female it may be due to an ovarian cyst with twisted pedicle and occasionally to a suppurative pelvic cellulitis, usually a post-puerperal infection that points above the lateral half of Poupart's ligament. A deep abscess of the abdominal wall, though rare, is occasionally seen in connection with an intra-abdominal malignant growth that has become adherent to the parietal peritoneum and is breaking down. In the male I have seen suppuration of the great omentum that has occupied the sac of a left-sided, incarcerated, inguinal hernia following reduction by rough and prolonged taxis. The etiology here as in appendicitis is infection. It may be well to remember that diverticulosis differs from diverticulitis in that it consists of a number of very small diverticulae of the transverse colon and the sigmoid and is not operative. Inflammation of a Meckel's diverticulum produces peritonitis, the cause of which can only be disclosed by operation. Oftentimes a case of strangulated hernia is reduced *en bloc*, that is, the hernial mass has been reduced but the symptoms persist. In such instances, the only alternative is operation. As I see it, and as a large hospital experience has taught me, taxis is a dangerous procedure, and is responsible for much of the high mortality in strangulated hernia. This is estimated at 50 per cent—entirely too high a mortality for strangulated hernia. What are the operative findings in many of these cases? Blood or bloody fluid in the sac, smears of which, with few if any

exceptions show streptococcus or the colon bacillus. Therefore the sac of a strangulated hernia should be evacuated and cleaned before dividing the constriction causing the strangulation, and thus prevent this poisonous fluid from entering the peritoneal cavity. Oftentimes taxis causes hemorrhage into the bowel wall and the mesentery, and precipitates gangrene. This makes a bowel resection, if necessary, more serious, in that more of the bowel as well as of the mesentery must be removed in order to get clear of the hemorrhagic, thrombotic area. If in all irreducible hernias, whether strangulated or not, operation in place of taxis were done early, the mortality would be reduced, I believe, to a very small per cent. Why then continue to teach taxis?

Acute intestinal obstruction occurring in the lower abdomen may be due to one of several causes, the more common of which are adhesions, the result of a previous abdominal operation, a congenital hole in the mesentery, impacted gallstone, neoplasm, or carcinomatous stricture. These are cases for immediate operation and not deliberation or medication. Look and act—not watch and wait (Moynihan). To medicate these patients places us in the class of life destroyers and not of life savers. Acute obstruction supervening upon chronic obstruction, as, for example, by a growth or annular stricture, usually carcinomatous in origin, is not a case for radical but for palliative operative work in the shape of a cecostomy. If warranted more radical work can be done later.

In the female the more common lower abdominal conditions, such as some form of salpingitis-hematosalpinx, pyosalpinx, hydro-salpinx, fibroid of the uterus, simple and dermoid cyst of the ovary are generally easily recognized. In the inflammatory conditions, the diagnosis, with few exceptions, can be made by the history, the presence of a vaginal discharge, and by bimanual examination including digital examination per vaginam and rectum, especially if the rôle of pelvic appendicitis is kept in mind. I stress this, as I frequently see pelvic appendicitis diagnosed inflammation of the uterine appendages. The differentiation is most important in the presence of an active pelvic peritonitis, in which precipitous abdominal operation may spell disaster. If by digital touch per vaginam there is definite evidence of a pelvic collection, incision only, through the roof of the vagina, posterior to the cervix at junction of latter with vagina, is the best operative procedure. To introduce the finger or fingers through the vaginal incision into the pelvis under such circumstances with the idea of finding and evacuating pockets of pus is a mistake. In making a vaginal examination in a nervous, apprehensive woman with pelvic pain, a sigmoid loop comparatively full of soft feces, may be mistaken for a tubal condition.

Another mistaken diagnosis that often occurs is to diagnose fibroid uterus where a subacute or

chronic pyosalpinx, with organization of the tubal and peri-tubular exudate and the tubes adherent to the sides and posterior surface of the uterus, produces a hard mass of considerable size associated with metrorrhagia or menorrhagia in women approaching middle life. This is not of serious moment, as abdominal operation should be made in any event. Both metrorrhagia and menorrhagia are frequent occurrences in these conditions, as well as in others, as in the presence of a large intra-ligamentary cyst, papilliferous cyst carcinoma of the ovary, tubo-ovarian disease, etc. Both curettage and radium are prohibited in any of these conditions. I seldom use radium in pelvic disease of women excepting in carcinoma of the cervix and then only in the late cases, but not in the very early cases. Although I use radium in the advanced cases of carcinoma of the cervix I have yet to see such a case that has been cured. This will strike some of you as perhaps a strange statement to make, but nevertheless this is my personal experience.

You may be interested to know my attitude as to the use of radium in conditions other than malignancy. I do not use radium in the treatment of fibroids of the uterus where operation is not contraindicated. I am sure that, in skilled hands, operation is attended by less mortality and less chronic morbidity than after treatment either by radium or x-ray. The selection of the case for the correct line of treatment, I believe, should be made by the abdominal surgeon of large and varied experience, and not solely by the strictly specialized roentgenologist or radiologist. Even then mistakes will occur. I feel very strongly about this, having seen many unfortunate occurrences, such as pelvic abscess, sepsis, fistulae, necrosis, etc., as the result of ill-advised radiotherapy. In this matter I feel much as I do regarding intravenous therapy practiced so generally and, as I do not hesitate to say, injudiciously. In the bleeding non-malignant uterus, in the absence of appendiceal disease, which no one can always be sure of, radium may be used, but the dosage should be such as not to destroy ovarian function. In pelvic operations in the female, we argue in favor of saving the ovaries when possible, therefore is the argument not equally strong when using radium? We read and hear much about transplantation of ovaries as well as giving ovarian and corpus luteum extracts to correct the condition brought about by the removal or destruction of the ovaries, therefore why take them out or destroy them when it is possible to leave them in?

Mistaken diagnosis of intra-ligamentary cyst, especially papilliferous cyst carcinoma of the ovary, is excusable. An intra-ligamentary cyst that is fixed and of smooth contour usually displaces the body of the uterus to the opposite side of the pelvis and, except in the absence of a much distended sac wall, will show a resiliency that suggests a fluid tumor. Papilliferous cyst

carcinoma of the ovary frequently is not diagnosed until the abdomen is opened. The important signs in a female past middle life are the presence of free or encysted fluid in the abdomen and by vaginal touch of an irregular hard mass behind and to the side of the uterus and cachexia or a color suggestive of a serious condition. To one who has not seen many of these cases metastatic carcinoma will most likely be the diagnosis. These patients, unless approaching extremis, should be operated. In fact, in my experience, with early operation life has been materially prolonged, so much so that the patients considered themselves well until a recurrence took place. In some cases I have operated a second time with further prolongation of life. The very late cases are hopeless, although in a small percentage operation may accomplish something. When the case is not too far advanced I make the operation a very radical one, removing, when possible, everything in the way of discrete masses. In fact, I have cut away an infiltrated great omentum, and where the body of the uterus, but not the cervix, is involved, have made a subtotal hysterectomy. Where there is considerable bloody oozing at operation I drain the pelvis with a glass tube which is removed the next day, or, at the latest, the second day after the operation. In some cases a lot of gelatinous material is encountered, this I remove by hand and by irrigation. I have taken out enough of this material to fill an ordinary-sized bucket. It is marvelous the improvement that takes place in some of these cases after operation. When asked to have these patients X-rayed after operation, I agree, but I have never seen any very good results.

In conclusion, let me say a word about the lower abdominal emergencies occurring in the woman, chief among which are ruptured extra-uterine pregnancy, tubal abortion and rupture of a blood cyst of the ovary in the young girl. In the first named, the diagnosis in most instances is made before the abdomen is opened, chiefly by the history, the appearance of the patient, the blood picture and the presence of a distinct wave of fluctuation upon the lightest palpation. I have demonstrated this to my internes many times. The characteristic point in reading the blood picture is the high leucocytosis. In the very early case we must not be led to defer operation on account of a fairly high hemoglobin and red cell count, as the blood does not show the picture of

anaemia for some hours after the occurrence of the catastrophe. To delay operation is, to put it mildly, dangerous. I have seen many patients, practically pulseless when put on the table, go safely through the operation, an intravenous saline solution being given while the operation was being done. Fortunately, the most important part of the operation, the arrest of the bleeding, is accomplished in a very few minutes. As soon as the peritoneal cavity is opened, the index and middle fingers of the left hand are carried into the cavity and after the fundus of the uterus is located the fingers glide along the upper border of the broad ligament and find the lesion, then by grasping and firmly compressing the broad ligament to the pelvic side of the lesion, a good-sized curved forceps is placed and the hurry is over and the bleeding controlled. In general, the most serious cases are those where the rupture of the tube takes place at its junction with the uterus. This was forcibly impressed upon me a number of years ago during the lifetime of the late Dr. Henry Formad, a famous pathologist connected with the University of Pennsylvania and Coroner's Physician of Philadelphia County, who used to say that the cases of ruptured ectopic pregnancy occurring at the utero-tubal junction were cases upon which he operated, while those of rupture of the body of the tube were cases for the surgeon to operate upon.

Before these patients are removed from the operating table the free blood and the blood clot are washed out of the abdomen with hot saline solution and enough of the solution is left in the abdomen to fill it. This stimulates the splanchnic vessels, has a good effect upon the sympathetic plexuses, and does away with the likelihood of sapraemia if the blood clots are not removed. To wait for recovery from shock before operating is too often to wait for the patient to die. A ruptured ovarian blood cyst in the young girl is not always recognized as such. This matters little if the seriousness of the hemorrhagic condition is recognized and immediate operation resorted to. In our experience in the Lankenau Clinic very few cases of ruptured extra-uterine pregnancy have had to have blood transfusion, although many require infusion of normal saline solution. We never use the free blood in the peritoneal cavity for transfusion—we do not think it perfectly safe.

## INDICATIONS FOR RADIOTHERAPY IN UTERINE LESIONS\*

By WILLIAM P HEALY, M D, F A C S, NEW YORK, N Y

**R**ADIUM as you know was discovered by M and Mme Curie in 1902. Within a few years thereafter it was realized that the gamma rays thrown off by the element were very valuable in the treatment of cancer and it soon came into very general use for the treatment of external or skin cancer.

The surgical treatment of cancer of the uterine cervix in the early part of this century was in a bad way. Simple cauterization of the lesion with the actual cautery, amputation of the diseased cervix with the cautery knife, vaginal or abdominal hysterectomy were all being tried but to no avail because of the rarity of early diagnosis.

The lesion almost invariably had extended beyond the uterus before it was recognized.

Wertheim in 1895 had developed his special operation, the plan of which was to remove by the abdominal route, not only the entire uterus and the adnexae but also the infected regional lymphatics and parametrial lymph nodes. This was a very serious operation, required considerable time, was associated with severe shock and very unpleasant postoperative complications and unfortunately a high operative mortality. In Wertheim's first one hundred cases 30 per cent died from the operation and it was difficult for even the most skilled operator to reduce the primary mortality below 20 per cent. Moreover only about one third of the cases seen were regarded as favorable for operation, the remaining two-thirds were given no worthwhile treatment and the picture closed for them very quickly.

Faced by such a distressing situation gynecologists throughout the world were quick to grasp at the possibility of help offered by the action of radium on tissues.

By 1913 medical literature began to contain many worthwhile articles from specialists of experience and distinction in Europe reporting cases of carcinoma of the cervix and vagina that had been regarded as beyond the hope of surgical treatment and nevertheless had responded remarkably well to the application of radium.

Naturally the cases on which this treatment was tried at first were the advanced cases. However, the response to treatment was so gratifying that soon earlier and more favorable cases were given the same treatment and finally cases that formerly would have been regarded as suitable for the Wertheim hysterectomy were instead treated by radium with or without x-ray treatment as well.

From 1913 the leading gynecologists throughout the world began to omit hysterectomy from the plan of treatment for carcinoma of the uterine cervix. Nevertheless there is still an operator here

or there who cannot refrain from hysterectomy despite the poor statistics which accompany it.

Weibel of Vienna who was Wertheim's assistant and is probably the best exponent of the radical abdominal hysterectomy that we have today reports that he is able to treat about 47 per cent of the cases he sees by operation and of those treated he reports 43 per cent of five year cures, but he entirely ignores his primary mortality of 166 per cent.

His figures actually show that five years after operation he can trace only 18 per cent of the cases operated on.

What has radiotherapy to offer against this?

In the first place the difficulty of making an early clinical diagnosis is not the serious handicap to radiotherapy that it is to the surgeon. In very few cases is it impossible to offer the patient some help at least temporarily with radium or x-ray.

Moreover the important fact must not be overlooked that in general the squamous epidermoid carcinoma that starts in the cervix is or tends to be a radio sensitive tumor and may respond to treatment much better even when clinically very advanced than one would dare to hope.

It must be borne in mind I repeat that with radiotherapy we treat practically all but the most hopelessly advanced cases whereas only one third to one fourth of the cases applying for treatment could be operated on surgically.

If we divide our cases into an early or favorable group in which the gross disease is restricted to the cervix and a less favorable or so called borderline group in which the disease has passed somewhat beyond the cervix to the adjoining vaginal fornix or parametrium, and a third or advanced group in which the disease has passed well beyond the uterus and there are definite metastases in the broad ligaments, we can discuss our results intelligently and compare them with those of the surgeon.

Statistics based upon results of less than five years duration are not of great value, therefore, our statistics refer to five year results.

Our early or favorable group is the one which corresponds to the operative group of the surgeon, 64 per cent of the cases in this group are alive and in good condition as against 23.7 per cent of Weibel's cases.

In our borderline group 38 per cent are in good condition.

Our advanced group shows 16 per cent in good condition and this we regard as a remarkable achievement for it is safe to say that very few of these cases had more than a year of life ahead of them without radiotherapy. Just as important is the fact which should always be borne in mind, that there is no mortality associated with the treatment.

\* Read at the meeting of the First District Branch of the Medical Society of the State of New York October 20, 1927.

We feel that these statistics place a very severe burden upon any surgeon who continues to treat cancer of the uterine cervix by hysterectomy.

On the other hand cancer of the uterine body is different in histologic type from cervical cancer, is of the glandular or adeno carcinoma variety, is usually slow in leaving the primary focus, does not always respond well to treatment with radium, occurs chiefly after the menopause, can be completely removed by operation and at the present time is best treated by complete hysterectomy.

So much for the malignant lesions of the uterus.

The benign conditions which are amenable to radiotherapy are the so-called idiopathic or myopathic uterine bleeding cases and the fibromyomata.

The myopathic bleeding cases occur chiefly in the years associated with the menopause and at a time when endocrine imbalance readily occurs. However, careful pelvic examination reveals no lesion except possibly a somewhat softened and heavy uterus, a curettage obtains considerable mucous membrane of the hyperplastic glandular endometrial type. Radium applied within the uterus in these cases is a specific and seldom requires a second application.

Diagnostic curettage should always be done so as not to overlook a possible cancer. If radium is not available x-ray may be used after the curettage. Excessive or prolonged menstrual bleeding at puberty or within the first year or two of menstrual life is not uncommon and will respond as a rule to general medical measures and endocrine therapy. In the more obstinate cases the patient often has to be kept in bed for some weeks before the bleeding is controlled by these measures. Occasionally despite the utmost effort and care the bleeding will continue to be excessive and it will be evident that something more radical must be done. Under such conditions I believe it is advisable to recommend curettage which will usually clear up the situation providing the other measures are continued.

Very rarely one will meet with an obstinate and persistent case in which even the curettage does not correct the disturbance, under those conditions I believe one may justifiably give a small dose of radium applied within the uterus but for a dosage of not more than 200 to 300 milligram hours. Great care should be exercised in the use of radium in these young girls for the uterus is usually rather small and both ovaries lie close to the posterior uterine wall and are well within the reach of the gamma rays from the radium.

In the treatment of uterine fibroids a definite and valuable field of usefulness has been estab-

lished for radium alone or in combination with x-ray. There are, however, definite contraindications to the use of radiotherapy in the treatment of these tumors.

Briefly they are as follows:

The tumor or the uterus with the tumors should not be larger than a size corresponding to a four months' gestation, there should be no evidence of adnexal disease, nor should there be any suggestion of degenerative changes in the tumors. The fibroids should not be of the pedunculated type either subserous or submucous.

Radium in my opinion is not desirable as a method of treatment for fibroids in women who are under 35 years of age unless there is some constitutional contraindication to surgery. The dosage necessary to control the growth of the ordinary tumor in a young woman would inevitably affect the ovarian function and would tend to bring on an artificial menopause. In these women it seems much better judgment to remove the tumors by myomectomy if possible or if necessary by supravaginal hysterectomy but conserving the adnexae. The risk of the operation is practically nil and the results of surgical treatment in young women are infinitely better because of the preservation of the ovarian function.

There is also a type of individual in whom radiotherapy is contraindicated because the psychology of the patient is such that she is not content unless the tumor has been surgically removed. It is evident from the preceding remarks the cases best suited to the treatment are those in which the tumors are small, intramural, unassociated with evidence of inflammatory disease and in which the patient's age is 40 years or more.

It is interesting to note that when one has radium available for the treatment of these tumors that many opportunities are found to use it with advantage to the patient, from the standpoint of minimum risk of operation, reduction in size of tumor or its complete disappearance and the relief of symptoms from the tumors. It is nevertheless my opinion that more patients with fibroids are treated to advantage by operation than by radiotherapy.

Occasionally there is a patient who is suffering from the annoying symptoms of fibromyoma and who should ordinarily be treated by operation but who has an intense horror of major surgery, such a patient as well as one in whom the tumors are complicated by serious cardio renal or other constitutional lesions can frequently be treated with radium or x-ray to advantage. In conclusion then one may say that a distinct field in the therapy of uterine lesions has been developed for radium and x-ray.

### FULFILLED IDEALS

The NEW YORK STATE JOURNAL OF MEDICINE completes the twenty-seventh year of its publication with this issue. It was established on January 1, 1901, by the New York State Medical Association, and was continued by the Medical Society of the State of New York after January 1, 1906, when the two state societies were merged. This JOURNAL has retained its original plans and policies unchanged, because its originators rightly

judged the aspirations of the physicians of New York State. The name of one founder, Dr. E. Eliot Harris, appeared on the official board of the first volume and of many other volumes up to the end of the past year. Dr. Harris lives to see the ideals, which to him and his co-workers were prophetic visions, evolved into actualities with the naturalness of a child coming into the fullness of its manhood.

## MOUNTAIN PEAKS OF MEDICAL PROGRESS

Progress in medicine is dependent on organizations, for without them every item of medical knowledge would die with its discoverer. The distribution of knowledge is dependent on an organization, such as teacher with a group of pupils, or a writer with a group of readers.

Modern societies of physicians are organized in order to promote two objects

- 1 The science of medicine
- 2 The art of medical practice

Scientific medicine emphasizes the disease which a patient has. It deals with the cold facts of physics, chemistry, physiology, anatomy and pathology. Examples of organizations dealing primarily with the scientific aspects of medicine, are the medical school, the research laboratory, the academy of medicine and the scientific congress.

The art of medical practice considers the patient as a person who is to be relieved, if possible, and comforted always. One who practices the art of medicine lights the torch of knowledge at an altar in a temple of medical science, and carries its beneficent rays into the homes of those who sit in the shadow of death. The practice of the art of medicine is a personal matter depending on the cooperation of two individuals—the doctor and the sick person. Examples of organizations which place the emphasis on the person rather than the disease are the staff of the hospital, and the medical society of the county, the state, or the nation.

The activities of the Medical Society of the State of New York have been principally along the lines of the art of the practice of medicine. It has left the discovery of new facts and methods to the research laboratories and the academies of medicine, but it has taken the new facts and methods and brought them to the attention of the physicians throughout the state. Its two ideals are

- 1 Every member shall have access to the medical knowledge that is developed by the research laboratories

- 2 Every person shall have the desire and means to avail himself of medical service

Medical service may be considered as a commodity.

Scientific medicine is produced by research workers in laboratories and academies of medicine.

Practicing physicians are the salesmen who distribute that knowledge to the people.

The people are the buyers and users of medical service.

Physicians are the producers and reservoirs of medical service, and are charged with the same responsibility that devolves upon the salesmen of a factory—that of rousing the people to desire to have what the doctors are distributing, and

of educating them how to use it when they get it. If physicians do not spread a knowledge of the value of their services, the people will patronize the cultists and quacks whose wares consist entirely of promises impossible of fulfillment.

Medical progress consists in raising the level of medical knowledge and practice. The usual course in the progress in any line is that an individual or group of original thinkers raises a branch of knowledge into a hilltop or mountain peak, towering above the knowledge possessed by the rest of the doctors, and then comes the slow task of bringing the knowledge of the other physicians and the people up to that height. The tableland of usual medical practice today is above the mountain peaks of knowledge of the half century ago, and the present peaks will be more deeply submerged in the future.

It has hitherto taken five or ten years to raise the knowledge of doctors up to the level of the peaks attained by the few, and a quarter of a century or more to raise the peaks of knowledge possessed by educated laymen up to the level of the tableland of knowledge of the average doctor. But during the past few years the Medical Society of the State of New York has put forth special efforts to speed up the rate of the distribution of knowledge from its fountainhead in laboratories and hospitals, to both practicing physicians and the people.

The past year has seen new peaks of progress raised by the State Society and new levels attained by the county societies. The progress has been along the three lines of production, distribution and utilization.

The outstanding peak attained by the State Society in the production of new ideas during the past year has been that of the leadership of the medical profession in all lines of the practice of public health and civic medicine. This idea was only timidly expressed as an aspiration ten or fifteen years ago. It was proved feasible and necessary by a few pioneer county societies, and has been loudly proclaimed during the past year, largely as the result of the action of the Cattaraugus County Medical Society, and the activities of the Committee on public relations of the state society.

A high peak of progress in the distribution of medical knowledge was raised in 1924, when the committee on Public Health and Medical Education announced a system of graduate education in which instruction was taken to the doctors in a few rural counties. The continuation of the work of raising the level of medical knowledge in other counties has gone on actively during the present year. The courses which have been given in several counties have not been intended to produce specialists in any line, yet their result has been to indicate the newer means of diagnosis and treatment and to show how they

may be obtained in time of need. The courses have revealed the peaks of medical knowledge to a large group of physicians, and have inspired family doctors to raise the level of their medical practice.

The utilization of the means of preventive medicine have been exemplified with striking success in the anti-diphtheria campaign which has reached its highest point during the past year. The mountain peak of knowledge of the protective value of toxin-antitoxin was raised over a decade ago, but the level of the medical plains and valleys was not perceptibly raised until about three years ago when the State Medical Society and the State Department of Health started a

joint campaign for educating the doctors to give the immunizations to school children and parents to accept them. The past year has seen a widespread cooperation of physicians and laymen in giving the immunizations in every part of the State, until communities have striven among themselves in a rivalry as to which should have the least diphtheria.

The mountain peak of progress in the preventive medicine raised by the anti-diphtheria campaign has stimulated physicians to undertake other lines of preventive medicine in order to raise the standard of medical knowledge among laymen as well as practicing physicians.

## LOOKING BACKWARD

### THIS JOURNAL TWENTY YEARS AGO

This JOURNAL of December, 1907, twelve years after the discovery of X-rays was first announced, has an article on "The present status of the Roentgen Rays" by Arthur Holding, M.D., of Albany, in which he says:

"Gone are the days of expensive experimenting as regards the type of machine to use, the days of dispute between the champions of the coil and the static machine, the days when we were content to listen to the seductive assurances of the electrical salesman followed by the failure of the machine to make good in our hands. Gone are the days of an X-ray room crowded with cumbersome apparatus, the days of fluoroscopic examinations, the days of X-ray burns, the days of 15-20 minute exposures.

"The surgeon who today says that the X-rays are unnecessary, that his "tactus eruditus" can tell him all that the X-rays could, "and more too," has taken his place with those who prefer to judge temperature by the hand rather than by the clinical thermometer, the blood by the pulse, rather than by the microscopical examination, and with the devotees of "laudable pus." The older methods have their value—long may they live—but the newer methods also have their value. To admit the value of one is not to deny the value of the other, long may they live together in the arma-

mentarium of the progressive medical profession.

"Radiography bears all the earmarks of a clinical laboratory method, *i.e.*, the required instruments are costly and delicate, they require an operator with technique to get satisfactory results, X-ray observations are of clinical value to the general profession, their therapeutic value is occasional rather than general, and should not be magnified. Clinical pathology and clinical bacteriology, especially the examination of throat cultures for diphtheria, have been conducted most practically in the public laboratory, accessible to all members of the profession, conducted by competent men, its processes available for student instruction, and so also will radiography yield more scientific results under similar surroundings.

The Roentgen rays are still the X- or unknown rays, although the generally accepted theory is that the wave lengths of this light are far shorter and their rate of vibration far more rapid than those of ordinary light. These short waves of light are destructive to the human organism, as witnessed by the development of carcinomata, and azoospermia among the X-ray operators. Therefore, today, the radiographer avoids all exposure to the rays. This has led to the passing of direct fluoroscopic examination."

## MEDICAL PROGRESS

**Insulin in the Treatment of Certain Hepatic Affections**—J Bamberger, of the Berlin City Hospital (Friedrichshaim) begins his article with the theoretical significance of insulin for diseases of the liver with special reference to the glycogenic function. In combination with glucose it has produced surprisingly favorable results on several of the serious organic diseases of the liver, both common and unusual. Under the latter head the author calls special attention to hepatic lesions which develop in the course of certain poisonings, notably phosphorus and toadstool. Years ago it was shown that intravenous glucose infusion was the sole remedy which could control the symptoms of poisoning by fungi (although a cure is not expected) and it is quite probable that the addition of insulin would give a further favorable effect. Recently the author had the opportunity to treat a case of acute phosphorus poisoning with this combination, the patient having swallowed rat poison with suicidal intent. The patient was under treatment in the hospital for nearly three months before he could be discharged cured. Phosphorus was abundant in the washings of the stomach and the clinical picture was complete with the occurrence in the urine of leucin and tyrosin. On discharge not only was the urine normal but tests showed that there was no hepatic insufficiency. A persistent tendency for the symptoms to reappear after improvement was persistently antagonized by a return to the treatment. — *Deutsche medizinische Wochenschrift*, September 30, 1927

**Insulin in Underweight**.—Schellong and Hufschmid of Professor Schittenheim's Clinic for Internal Medicine, University of Kiel, sum up the progress in this direction while at the same time giving the experience of their own clinic. Their management consists mainly in the combination of small doses of insulin with timely feeding with carbohydrates until a stationary weight is attained. If greater weight is desired it may then become a question of giving larger doses of insulin. The substratum of carbohydrate food upon which the insulin can act is a prerequisite and if for any reason this is not forthcoming the desired result will not be obtained. Just before and after an insulin injection the patient receives special rations of easily assimilable carbohydrates, as bread with honey or sugar and even pure lump sugar. The class of patient to benefit by this treatment is affected with constitutional leanness and small appetite, condi-

tions which point to insufficiency of the Langerhans islets of the pancreas. The effects of the first injections—even at times of one injection—may be striking. The islets show their stimulation by setting up an intense hunger whereupon large quantities of carbohydrate foods are demanded. The patient is not only hungry at meal times but between meals. Water retention is promoted and weight is put on rapidly. A condition of equilibrium is reached toward the close of the second week, as apparently the subject becomes in part habituated or immunized against the further action of the insulin. Most authorities have employed larger doses than the authors because the intention is always to give but few injections, at Kiel, however, the rule has been to give only two injections of 10 units each at the outset, then if the result warrant the same doses may be given indefinitely, week after week, and it is not necessary to increase the dose although this possibility may come up later. — *Klinische Wochenschrift*, October 1, 1927

**Ferrán's Doctrine of Tuberculosis and the Antialpha Vaccine**—Dr Martin Salazar refers to the commanding position of Ferran in Spain as a sanitarian, phthisiologist, bacteriologist and immunologist. He has been at work for many years on the problem of tuberculosis—he in reality is a contemporary of Koch himself—and has reached various conclusions which are not in entire harmony with those of the medical profession. For some unknown reason his views are too little known to the world at large. One of these has reference to peculiar mutations of the bacillus which result in harmless as well as pathogenic forms. He has isolated numerous strains which he distinguishes by letters of the Greek alphabet, as alpha, delta, epsilon and so on. Some of these are resistant to acids, others not. The original microorganism, the alpha bacillus, is of the latter type. Inoculated into animals in pure culture it causes the formation of tubercles. The mutations may be divided further into ascending and descending—progressive and regressive—the former comprising the alpha, beta and gamma forms. It is the alpha form which prevails extensively in nature as a saprophyte and parasite. It attacks the young by thousands but by reason of its mutations certain phenomena develop, through which it loses some of its characteristics, including virulence. Differences are evident in the toxic products, for while some toxins cause inflammation and antibody formation—in other

words are allergic—others containing lipoids are without this action. In its mutations the bacillus goes through a cycle, for the epsilon bacillus at the end of the series mutates back into the alpha form, both being non-acid-resistant. The anti-alpha vaccine of the author is prepared from these two forms jointly. This has passed the experimental stage, for it has been in use since 1920 and during this time as a result of attempts at immunization, the mortality from tuberculosis in the Foundling Hospital at Buenos Aires, so the writer states, has now been reduced to zero.—*El Siglo Medico*, September 24, 1927

**Vaccination of the Newborn Against Tuberculosis**—B Iakhnis states that inoculation of the newborn with Calmette's serum was begun at Kharkoff toward the middle of September, 1925. Nineteen months later he is reporting progress, on behalf of the Ukraine Commission which is sponsor for the movement. The latter was not sanctioned by the Commission until after due investigation on animals. Newborn to the number of 300 in the three maternities of Kharkoff were the first subjects, the full consent of parents having been obtained. The tuberculous gravidæ and those who lived in contact with the disease in their families were indicated in advance, although unfortunately there were numerous cases which went unrecorded through defective organization of the movement. Preference was always given to children most exposed to the disease. Enough other newborn were vaccinated to bring the gross total up to 472 during the space of 18 months, and of this number 26 died of the ordinary diseases of nurslings while 42 others were lost from observation. The number available for statistics is, therefore, 402 of whom 156 had not been in known contact with the tuberculous, 112 had been in contact with suspects only, 95 with active tuberculous subjects, and 41 with subjects with continuous or intermittent open lesions. Of the 26 deaths mentioned above only one was from tuberculosis. The other causes of death comprised acute intestinal disorders (10), grippe-pneumonia (7), and scattering, with but one case set down to unknown cause. This mortality of one tuberculous death in so many children over so long an interval is strikingly low. No ill effects from the vaccination have been seen. The children are shown to have developed within normal limits, over 92 per cent being free from all dystrophies. The only method of checking up thus far has been the tuberculin reaction which has been practised on a limited number, positive reactions being 10 times as common as in the unvaccinated. Naturally there will have to be a

survey of a large number of unvaccinated newborns as a control.—*Annales de l'Institut Pasteur*, October, 1927

**A Clinical Study of the Alkali Treatment of Scarlet Fever**—E H J Berry quotes from the literature evidence proving that alkalis very considerably lower the incidence of nephritis. The records of 2,819 cases of scarlet fever show that scarlatinal rheumatism and albuminuria are related to the extent of 27.5 per cent, while scarlatinal rheumatism and endocarditis are related to the extent of 17.3 per cent. Since albuminuria and rheumatism are so strongly related, and the incidence of nephritis can be lowered by the alkalis, it is reasonable to suppose that the incidence of scarlatinal rheumatism can be appreciably lowered by the alkaline treatment. If the incidence of scarlatinal rheumatism can be appreciably diminished, it follows that the incidence of cardiac complications can be lessened. Proceeding on the basis of this argument, Berry has become convinced of the beneficial effects of alkalis in toxic cases of scarlet fever, and believes that all cases of this kind should be treated in a similar manner. He reviews the first 100 unselected cases treated by alkalis, of these only one developed albuminuria and one albuminuria and rheumatism while on alkalis. The mixture given contained 40 grains of potassium citrate and 40 grains of potassium bicarbonate to the ounce of water. In toxic cases treated energetically with alkalis a marked change occurs in from 24 to 36 hours. The urine no longer gives a ferric chloride reaction, the tongue becomes moist, the rash becomes vivid, delirium disappears, and the temperature falls by crisis. If the child cannot swallow, the alkalis must be given by rectum. The quantity of alkali required to render the urine alkaline in a toxic case is surprising, one child, aged 5, required 640 grains in 24 hours. Berry has not seen such a marked benefit as that portrayed above from the use of serum.—*Lancet*, October 22, 1927, ccxiii, 5434

**Diphtheria Gravis**—H Schmidt, director of the Behring Institute at Marburg, says that within the past year there have been very severe cases of diphtheria in Berlin and other large cities which have caused the fear that the disease is about to undergo a recrudescence with all of the old malignancy of fifty years ago. In some of these cases the serum appeared to be deficient in antidoting properties. In regard to the claim of mixed infection with streptococci as the cause of malignancy the author states that he saw the slides from nine of these patients in the Rudolf-Virchow Hospital, Berlin, and that all

showed the diphtheria bacillus in pure culture. The strain of bacilli was quite malignant to guinea pigs and the autopsy finds on the human patients were characteristic of diphtheria. The author theretore repudiates the mixed infection hypothesis, and as a matter of fact it has always been impossible in the laboratory to enhance the virulence of the diphtheria bacillus by mixing it with other virulent organisms. The problem of the moment is to prepare a serum from this particular strain of the bacillus, also perhaps, to prepare a polyvalent serum if any other organism is really able to increase the virulence of the toxin. Still more important is the induction of the toxin-antitoxin active immunization which is being successfully carried out in both Great Britain and the United States but which—no one knows why—still hangs fire in Germany. There is also a likelihood that the doses now given, large though they be, may be too small.—*Deutsche medizinische Wochenschrift*, Oct 21, 1927

**Diphtheria, Septic Diphtheria, and Septic Angina with Diphtheria Bacilli**—Professor H. Dold sums up an article with the above title as follows: Acute tonsillitis with presence of diphtheria bacilli is not always diphtheria. This association may mean one of three possibilities—true diphtheria, mixed or septic diphtheria, or a septic or toxic angina in which diphtheria bacilli are accidentally present. From the practical angle, however, we cannot uphold this distinction and in any angina with presence of diphtheria bacilli one should notify, isolate, and give antitoxin. The latter produces a strikingly positive effect in true uncomplicated diphtheria, while in the mixed form the action is restricted, and in the third form no direct action should result. Apparent antitoxin failure means that the disease was of the second or third type or both conjoined. It is important to make a correct diagnosis but this is possible only through repeated cultures by which we may isolate the actually virulent organisms. When other organisms are associated with the diphtheria bacillus, we should never regard them as accidentally present. Among the pathogenic microbes which are found in this association are streptococci, staphylococci, *B. coli*, *B. pyocyaneus*, the Friedlander group, and several other less known organisms. The author reports five cases in which the streptococcus and staphylococcus were both present, although in three of them the staphylococcus was avirulent. Both organisms were shown to be hemolytic in two patients. The constant presence of virulent streptococci in these cases explains both mixed diphtheria and septic sore throat in which diphtheria bacilli are present in avirulent state.

However we must not take this presence of virulent streptococci as inevitable, for in exceptional cases we find highly virulent Friedlander (pneumo-bacillus) organisms, to say nothing of other possibilities.—*Deutsche medizinische Wochenschrift*, October 14, 1927

**A New Conception of Periodic Vomiting in Children**—Professor A. Uffenheimer of the Pediatric Clinic, Magdeburg City Hospital, gives a resume of this affection from the French and American viewpoints, and admits that for some reason the Germans have been laggards in this direction. He appends a most exhaustive case history with roentgen controls and, although he has but few cases to generalize from, he believes that our knowledge of this condition must be partly rewritten. Thus an acidosis is not always present, but there is a spasmodic condition of the stomach which suggests tetany. Comparison with cases reported by Kerley of New York, Gerst, and others shows that acidosis may not appear until several days after vomiting and it is even suggested that the inanition and dehydration which result from emesis are themselves sufficient to cause the acidosis. In Kerley's case the stomach was thought to have been prolapsed but the roentgen picture agrees strikingly with that in the author's case. The stomach condition itself appears to be a development of secondary nature. The syndrome points to a vagus disturbance, and a spastic closure of the pylorus might account for the distention spasm and ptosis of the stomach with vomiting as a natural consequence. At present the evidences of acetone poisoning must be relegated to a secondary position and the first motive referred to an endocrine and vagotonic condition associated with tendency to spasmophilia. The entire gastroenteric tract seems to be involved in the tetanoid condition, but spasm of the pylorus accounts best for the vomiting. The author does not mean to explain all cases of cyclical vomiting of children in this manner, for this crude symptom may also develop in other basic conditions. He is silent as to treatment tests and the possibility that this condition, if vagotonic, might yield to the Solanaceæ alkaloids, as in the case of sea sickness, etc.—*Muenchener medizinische Wochenschrift*, October 14, 1927

**Some Practical Points in the Treatment of Ringworm with Thallium**—After recounting the advantages of thallium epilation over x-ray epilation, J. H. Twiston Davies points out that thallium has a unique action on the hair of the scalp, and also on the sympathetic nervous system. It facilitates the passage of impulses through the synapses of the sympathetic nervous system, acting in much the

words are allergic—others containing lipoids are without this action. In its mutations the bacillus goes through a cycle, for the epsilon bacillus at the end of the series mutates back into the alpha form, both being non-acid-resistant. The anti-alpha vaccine of the author is prepared from these two forms jointly. This has passed the experimental stage, for it has been in use since 1920 and during this time as a result of attempts at immunization, the mortality from tuberculosis in the Foundling Hospital at Buenos Aires, so the writer states, has now been reduced to zero—*El Siglo Medico*, September 24, 1927.

**Vaccination of the Newborn Against Tuberculosis**—B. Iakhnis states that inoculation of the newborn with Calmette's serum was begun at Kharkoff toward the middle of September, 1925. Nineteen months later he is reporting progress, on behalf of the Ukraine Commission which is sponsor for the movement. The latter was not sanctioned by the Commission until after due investigation on animals. Newborn to the number of 300 in the three maternities of Kharkoff were the first subjects, the full consent of parents having been obtained. The tuberculous gravidæ and those who lived in contact with the disease in their families were indicated in advance, although unfortunately there were numerous cases which went unrecorded through defective organization of the movement. Preference was always given to children most exposed to the disease. Enough other newborn were vaccinated to bring the gross total up to 472 during the space of 18 months, and of this number 26 died of the ordinary diseases of nurslings while 42 others were lost from observation. The number available for statistics is, therefore, 402 of whom 156 had not been in known contact with the tuberculous, 112 had been in contact with suspects only, 95 with active tuberculous subjects, and 41 with subjects with continuous or intermittent open lesions. Of the 26 deaths mentioned above only one was from tuberculosis. The other causes of death comprised acute intestinal disorders (10), gripp-pneumonia (7), and scattering, with but one case set down to unknown cause. This mortality of one tuberculous death in so many children over so long an interval is strikingly low. No ill effects from the vaccination have been seen. The children are shown to have developed within normal limits, over 92 per cent being free from all dystrophies. The only method of checking up thus far has been the tuberculin reaction which has been practised on a limited number, positive reactions being 10 times as common as in the unvaccinated. Naturally there will have to be a

survey of a large number of unvaccinated newborns as a control—*Annales de l'Institut Pasteur*, October, 1927.

**A Clinical Study of the Alkali Treatment of Scarlet Fever**—E. H. J. Berry quotes from the literature evidence proving that alkalis very considerably lower the incidence of nephritis. The records of 2,819 cases of scarlet fever show that scarlatinal rheumatism and albuminuria are related to the extent of 27.5 per cent, while scarlatinal rheumatism and endocarditis are related to the extent of 17.3 per cent. Since albuminuria and rheumatism are so strongly related, and the incidence of nephritis can be lowered by the alkalis, it is reasonable to suppose that the incidence of scarlatinal rheumatism can be appreciably lowered by the alkaline treatment. If the incidence of scarlatinal rheumatism can be appreciably diminished, it follows that the incidence of cardiac complications can be lessened. Proceeding on the basis of this argument, Berry has become convinced of the beneficial effects of alkalis in toxic cases of scarlet fever, and believes that all cases of this kind should be treated in a similar manner. He reviews the first 100 unselected cases treated by alkalis, of these only one developed albuminuria and one albuminuria and rheumatism while on alkalis. The mixture given contained 40 grains of potassium citrate and 40 grains of potassium bicarbonate to the ounce of water. In toxic cases treated energetically with alkalis a marked change occurs in from 24 to 36 hours. The urine no longer gives a ferric chloride reaction, the tongue becomes moist, the rash becomes vivid, delirium disappears, and the temperature falls by crisis. If the child cannot swallow, the alkalis must be given by rectum. The quantity of alkali required to render the urine alkaline in a toxic case is surprising, one child, aged 5, required 640 grains in 24 hours. Berry has not seen such a marked benefit as that portrayed above from the use of serum—*Lancet*, October 22, 1927, ccxiii, 5434.

**Diphtheria Gravis**—H. Schmidt, director of the Behring Institute at Marburg, says that within the past year there have been very severe cases of diphtheria in Berlin and other large cities which have caused the fear that the disease is about to undergo a recrudescence with all of the old malignancy of fifty years ago. In some of these cases the serum appeared to be deficient in antidoting properties. In regard to the claim of mixed infection with streptococci as the cause of malignancy the author states that he saw the slides from nine of these patients in the Rudolf-Virchow Hospital, Berlin, and that all

# LEGAL

By LLOYD PAUL STRYKER, Esq.  
Counsel, Medical Society of the State of New York

## RECENT APPLICATIONS OF THE STATUTE OF LIMITATIONS TO MALPRACTICE ACTIONS AND COUNTERCLAIMS

Among the problems that confront the physician is the economic one of being compensated for services rendered. A physician oftentimes finds that after he has most conscientiously labored in behalf of a patient, payment for the services rendered is refused by the patient and a claim is made that the services were not either worth the amount asked by the physician, or that they were improperly rendered causing injury and damage to the patient.

Claims of this nature are presented by the unscrupulous patient, or those who are dissatisfied with the results of the treatment they have received, even when such result may be the natural, inevitable result of their injury or sickness.

To enforce the collection of his bills the physician must often resort to the institution of an action against the patient. It is a growing custom among some patients, in an attempt to thwart the physician and to avoid payment of his bill, when sued by the physician, to interpose a counterclaim of alleged malpractice, or else start a separate malpractice action and procure a stay of the trial of the physician's action to recover for his services until the malpractice action has been disposed of. A judgment in favor of the physician in the action instituted by him to recover for his services can be set up as a bar to a future action by the patient charging alleged malpractice in the performance of those services.

In a recent case a physician who had rendered services to a patient, and who after completion of the services, had sent numerous bills, was paid only a small part of his fee. His requests for payment being unanswered, he finally instituted a suit against the patient to recover the balance of his bill. After denying that the physician's services were worth the amount that he had requested, the patient in answer to the physician's action, interposed a counterclaim of alleged malpractice. She charged that the physician had undertaken to cure her of gall-stones from which she then suffered, but that through his negligence and carelessness he had diagnosed her malady as cystitis and treated her for such condition instead of diagnosing and treating her for a malady of gall-stones. The answer of the patient containing this counterclaim of malpractice was interposed to the physician's action more than two years after the services had been rendered by the physician. The physician in his reply

to the counterclaim pleaded the two-year Statute of Limitations, which provides that an action for malpractice must be commenced within two years after the cause of action accrues. Thereafter, on behalf of the physician, a motion was made to dismiss the malpractice counterclaim on the ground that it was barred by the Statute of Limitations. In opposition to this motion the patient contended that as the cause of action contained in the counterclaim arose out of the same transaction or subject of transaction of which the physician's action to recover for his services arose, the two-year Statute of Limitations did not apply, but that the patient was entitled to the benefit of the same Statute of Limitations as was applicable to the physician's action, to wit the six year Statute of Limitations. The lower court determined the motion favorably to the patient and denied the physician's motion to dismiss the counterclaim. The lower court in the course of its opinion said:

"The cause of action alleged in the counterclaim arose out of the original transaction upon which plaintiff bases his demand for judgment. If a cause of action survives to plaintiff from this transaction, then the defendant is entitled to assert any right or remedy that accrued to her from the same transaction. The legal effect of the transaction to the parties so far as they make demand in their pleadings must be determined. The rights and remedies of the same parties arising out of the same transaction cannot be divided and separated and some preserved and others cast out.

"When the plaintiff commenced this action he invited the defendant to take advantage of any infirmity that effected the transaction which is the subject of this litigation, even though defendant would be barred from instituting an independent action for the relief sought in the counterclaim."

If this decision had been permitted to stand, or was affirmed by an appellate court so that it became the law of this State, it would deprive not only physicians but others as well of a most valuable right, and no matter how long a physician might wait after the rendition of services before instituting an action to collect for such services there could always be interposed against such action a counterclaim of alleged malpractice. So that the effect of the decision would be to extend the Statute of Limitations from two years

same way as strychnine does in the central nervous system. The technique employed in the treatment of ringworm in children consists in weighing the child without clothing and administering a dose of thallium acetate to the amount of 875 milligrams per kilo of body weight. A fresh preparation of the drug is given in a solution of sugar and water. The hair is cut to about one-half inch in length, but no shorter. The head is washed on alternate days for six days and then daily. Infected areas are not interfered with, but the rest of the scalp is rubbed with an antiseptic (non-mercurial) ointment after the daily shampoo. As soon as the hair is found to be loose, the infected hairs must be extracted one by one with lens and forceps. Depilated areas are painted with 4 per cent tincture of iodine three times a day for four days. As soon as the scalp is quite bald, about the twentieth day, its entire surface is painted with the 4 per cent iodine tincture three times daily for four days, and then rubbed with some non-mercurial ointment (e.g., ung. sulphuris) for three days. The iodine sequence is continued for three weeks, the scalp being examined once a week at least, and then discontinued in favor of daily rubbing with equal parts of oil of cade, vaseline, and lanoline until the new hair is well established. In the process of depilation care must be exercised to discriminate between infected stumps and new hairs, which appear about the thirtieth day. A cotton cap, changed morning and evening is worn during the entire period of treatment, and other precautions are taken to prevent the spread of the infection. Children in whom alopecia areata complicates ringworm are unsuitable for thallium treatment.—*British Journal of Children's Diseases*, July-September, 1927, xxiv, 283-285.

**Cure of Warts and Condylomata by Suggestion**—J. Bonjour refers to the remarkable results recently reported by Professor Bloch of Zürich who cured 55 out of 109 cases of verruca vulgaris and 33 out of 38 cases of flat wart by this method. There is some chance for difference of opinion here as to the nature of the mental process involved, for it makes a considerable difference whether the physician uses simple suggestion in the restricted sense or affects the airs of a sorcerer and so makes the patient believe that he is the subject of a miracle. The present author, in his work along this line, makes use only of suggestion and has extended the treatment of these cases to include papillomata and condylomata. All of these four types of lesion are of a common nature. One patient with condylomata sent by a colleague had been "cured" once by röntgen treatment but had relapsed. Caustery appeared to aggravate and the patient presented numerous new formations on the lips and anus. In connection with suggestion in this

case, the author, in taking the blood pressure, noted that a fall took place in the minima. This he puts forward as a mechanism by which suggestion acts on the growths through the circulation. It is said that the same result may be obtained by the local injection of ergotin or adrenalin or other vasoconstrictor, but the author thinks that suggestion certainly possesses advantages over these methods. In most cases patients who present these formations are hypertensives and at times come of hypertensive families. In fact, Bonjour knows of but two cases in which the tensive minima were normal. The author does not give the precise technique of suggestion applied, but states that the simple word suffices and that one session should be sufficient. While he has had 35 years' experience he learned of the mechanism only about ten years ago. He believes that suggestion ought to cure 95 per cent of these patients.—*Schweizerische medizinische Wochenschrift*, October 8, 1927.

**Superiority of Certain Bismuth Combinations as Antisymphilitics**—H. Müller and his associate Kohlenberger of Mainz, mention the present day enthusiasm of many practitioners over bismuth as a remedy for lues. This does not mean that mercury has become obsolete or arsphenamine underestimated. The competition is a useful and constructive one, for chemists are also seeking new forms in which to exhibit the older remedies. Bismuth therapy sustained an advance when the metal was rendered soluble in lipoids by lecithin addition, such a preparation being preferable to a suspension. Lecithin itself was tested as an antisymphilitic by Peritz in 1908. A form of bismuth which has been combined with lecithin is the iodo-bismuth-quinine combination and the resulting preparation appears to be from four to six times more powerful as a spirocheticide than the same without lecithin addition. Much work has been done with this combination by Hermann and Nathan. It is true that there have been a great many bismuth preparations and combinations on the market but the one under consideration represents a solution in place of a suspension, and according to its elaborators many of the habitual defects of the bismuth preparations have been minimized. The soluble combination can be injected into the muscles and hence the technique of intravenous administration with the coincident need of experts and hospital facilities is eliminated. There is neither pain nor after-pain. But two cases of stomatitis were seen in over 600 cases and the bismuth seam on the gums was present in light form. The advantages of the iodo-bismuth-quinine formula have already been shown independently and the oil basis of the solution remains quite clear.—*Münchener medizinische Wochenschrift*, September 2, 1927.

plaintiff and failed to remove the broken needle a new claim arose in favor of the patient

In determining the motion favorably to the physician and in passing upon the plaintiff's contention, the Court said

"The wrong complained of was the failure of the defendant to perform a certain duty which he owed to the plaintiff. The question therefore arises how long that duty continued. It cannot be urged that the duty exists at present and that it will continue indefinitely until the cause of action abates by the death of either of the parties. If the contention of the plaintiff were sound the Statute of Limitations could not at any time be invoked as a bar to this action. It is more reasonable to assume that the duty, regardless of the question whether or not a failure of performance constituted actionable negligence, continued throughout the period of the treatment by the plaintiff at the hands of the defendant, and the latest period at which it could be expected that such duty would be performed and where failure of performance might constitute negligence was the occasion of the final treatment of the plaintiff by the defendant. Under the circumstances it seems that although the plaintiff's contention that the tort continued beyond the first day of June is good, the facts indicate that the tort did not continue beyond the 20th day of July, which was itself more than two years before this action was brought. It is the opinion of this court that although the tort continued to July 20th, it did not continue beyond the date, and that on the latter date the cause of action of the plaintiff accrued, and that the Statute of Limitations as sought to be invoked herein clearly applies."

In another instance, a patient suffering from a duodenal ulcer had consulted a surgeon. Nearly five years had elapsed from the time of the surgeon's treatment of the patient until the bringing of a malpractice action. In his complaint the plaintiff sought to charge the defendant with a breach of contract, hoping thereby to avoid the two-year Statute of Limitations applicable to malpractice actions, and invoke the six-year Statute of Limitations, applicable to contract actions.

In his complaint the plaintiff alleged that at the time he consulted the physician and surgeon he was suffering from a duodenal ulcer, and that he entered into an agreement with the surgeon

wherein and whereby for the consideration of one hundred and fifty dollars, to be paid to the surgeon, the surgeon agreed to perform a surgical operation for the removal of the duodenal ulcer. The plaintiff alleged that he performed all the provisions of the contract upon his part to be performed, but that the defendant surgeon failed and neglected to perform his part of the agreement in that he failed and neglected to remove the duodenal ulcer from the body of the plaintiff, permitting it to remain therein, and instead removed the appendix. In his complaint the plaintiff sought damages for pain, suffering, mental anguish and moneys claimed to have been expended for other medical and surgical care. He also claimed that he was prevented from attending to his usual vocation for a long period of time. To this cause of action a motion was made to dismiss the complaint on the ground that it stated a cause of action of malpractice, and that it was barred by the two-year Statute of Limitations. The plaintiff contended that his action was not one of malpractice but one for breach of contract, and that the six-year Statute of Limitations applied. The lower court denied the defendant's motion to dismiss the complaint. An appeal was taken by the defendant to the Appellate Division. That court examined the allegations of the complaint and said

"While in the complaint now under consideration neither lack of skill nor negligence is charged, the basis of the charge is 'improper performance' of the work to the personal injury of the plaintiff."

It was further held by the Appellate Division that the damages asked by the plaintiff, \$50,000, for pain and suffering were not suited to an action for breach of contract, and in reversing the decision of the lower court the Appellate Division concluded

"The nature of the charge of malpractice is not changed by failing to sufficiently state it in necessary detail, or by putting it in language suitable to the statement of a cause of action on contract, omitting the usual allegations as to the absence of skill and negligence."

From these recent decisions it will be seen that there has been preserved to the physician valuable rights in opposing and successfully defending malpractice actions or counterclaims which have not been instituted within two years after the cause of action accrued.

to six years, when the claim of alleged malpractice was interposed as a counterclaim - To determine the correctness of this decision we took an appeal to the Appellate Division which happily has reversed the order of the lower court and granted the defendant's motion dismissing the counterclaim

The Appellate Division after reviewing the authorities upon which the decision of the lower Court was based said

"The counterclaims in those cases, not only arose out of the contracts of the plaintiffs but were parts of those contracts. The plaintiff in each of those actions was attempting to sever the contract and to enforce part and repudiate the balance. It was simply held that the contract must be enforced in its entirety. The plaintiff was not at liberty to divide the contract and enforce a portion thereof favorable to himself, but was required to stand or fall on the entire contract."

With respect to the answer of the defendant denying the value of the services rendered, it was held that the defendant under such denial may prove the alleged malpractice of the plaintiff to show that the services were not of the reasonable value claimed by the plaintiff.

In its decision the court construed the application of a section of our Civil Practice Act which provides

"A cause of action other than for the recovery of real property, upon which an action cannot be maintained as prescribed in this article, cannot be effectually interposed as a defense or counterclaim."

On behalf of the defendant it was contended that the provisions of this section gave an unfair advantage to the plaintiff and permitted him to prosecute his cause of action, although a counterclaim in favor of the defendant arising out of the same transaction or subject of action was barred by the Statute of Limitations. It was further contended that the provisions of this section should not be held to apply to counterclaims of this nature.

In answering this contention of the defendant the Appellate Division said with reference to the above section of the Civil Practice Act

"Its phraseology could not be more comprehensive. It not only outlaws a counterclaim but also a 'defense'. A cause of action barred by the Statute of Limitations cannot be interposed as a *defense* or a counterclaim \* \* \*. The language of Section 61 is sweeping and the intent thereof seems fairly to have been to outlaw all defenses or counterclaims pleaded, as such which could not be the subject of an affirmative action."

By this decision of the Appellate Division there is preserved to the physician the right to plead the bar of the Statute of Limitations when a malpractice claim is interposed as a counterclaim

to an action for services rendered where the cause of action contained in the counterclaim did not accrue within two years prior to the assertion of the counterclaim.

In instances where physicians have not been paid for their services rendered, and where the result of their treatment has not been up to the expectations of the patient, or where the patient is dissatisfied with the services and there is a likelihood that in the event the patient is sued to recover for services rendered there would be an assertion of a counterclaim of alleged malpractice, it would be wise that the physician wait until at least two years after the rendition of his services before instituting suit against the patient, so that in the event that a counterclaim is interposed the two-year Statute of Limitations may be pleaded in bar to such counterclaim.

Statutes of Limitations are not new in our system of jurisprudence, and we have had such statutes limiting the time within which various types of actions can be commenced for hundreds of years. The purpose of such statutes is to restrict the period within which the right of action, otherwise unlimited, might be asserted. Such statutes have been founded in part at least on the general experience of mankind that claims which are valid are not usually allowed to remain neglected, and that the lapse of years without any attempt to enforce a demand prevents a judgment against its alleged validity. The object of Statutes of Limitations is to suppress the assertion of stale claims when all the proper vouchers and evidence are no longer in existence, or the facts have become obscure through the lapse of time, defective memory, death, or the removal of witnesses.

The patients who feel that they have been aggrieved by the services rendered them by a physician have at times resorted to various means to circumvent the Statute of Limitations where they have delayed longer than the statutory period in the commencement of a malpractice action.

In one instance a plaintiff had been under treatment of a physician from the 3rd of June to the 20th of July, and in a malpractice action instituted against the physician two years from the following September, it was charged that through the negligence of the physician and in the course of his treatment a needle broke and was permitted to remain within the patient's body. In answer to this claim on behalf of the physician a motion was made to dismiss the complaint on the ground that more than two years had expired since the cause of action stated in the complaint had accrued, and that therefore the same was barred by the Statute of Limitations.

On behalf of the plaintiff it was contended that the tort or wrong of the physician was a continuing one in that each day that he treated the

smallpox be made compulsory for all school children of the State of New York

2. The Madison County Medical Society favors County Health Organizations, but does not believe that the present County Health Unit plan as advocated would be suitable or ideal for Madison County, without further consideration of the matter

President E L Finley gave a résumé on past, present and future activities of the Society, with special reference to the practice of public health and civic medicine

Dr Edwin MacFarland of Utica gave an interesting paper on "Methods of Urological Examination"

D H CONTERMAN, M D, *Secretary*

---

## SARATOGA COUNTY

The annual meeting of the Saratoga County Medical Society was held at the Homestead Sanatorium, Middle Grove, N Y, November 2

Following a bounteous dinner given by the Board of Managers and Dr Asa Dimock, Superintendent, the scientific program was given

Dr George Beilby, Albany, N Y, gave an interesting lecture on Goitre.

The following officers were elected

President, Thomas J Goodfellow, M D, Saratoga Springs, N Y

Vice-President, F F Gow, M D, Schuylerville, N Y

Secretary, R. B Post, M D, Ballston Spa, N Y

Treasurer, John W Mabey, M D, Mechanicsville, N Y

Delegate to N Y Convention, Earl King, M D, Saratoga Springs, N Y

Alternate Delegate, J MacElroy, M D, Jonesville, N Y

Committee Minora, E J Callahan, M D, Schuylerville, N Y, G Scott Towne, M D, Saratoga Springs, N Y, D Mauro, M D, Mechanicsville, N Y, M J Cornthwaite, M D, Ballston Spa, N Y, L A. Parmenter, M D, Corinth, N Y

Censors, A W Porter, M D, F F Gow, M D, George Fish, M D

The applications of Dr Mark D Duby, Schuylerville, N Y, and Dr Asa Dimock, Middle Grove, N Y, having been received and passed by the Board of Censors, they were elected to membership in Saratoga County Medical Society

The report of the special committee to investigate defects among school children was read and approved

R. B Post, M D, *Secretary*

---

## GENEVA ACADEMY OF MEDICINE

The third annual dinner meeting of the Geneva Academy of Medicine was held in the Hotel Seneca, Geneva, on the evening of Wednesday, November 9th. The attendance was 190 physicians and surgeons from Geneva and the surrounding territory, some coming from the neighboring county secretaries, and some from Syracuse, Rochester and Buffalo

The program of the meeting was opened by Dr Harry Trick of Buffalo, President-elect of the Medical Society of the State of New York. He brought the greetings of the State Society and congratulations on the excellent support

shown by the members of this Academy, the latest one to be formed in the State

Dr George W Crile of Cleveland, Ohio, gave an address on the "Clinical Aspects of the Goiter Problem". The discussion was opened by Dr Martin B Tinker, of Ithaca, and Dr Donald Guthrie, of Sayre, Pa. The discussion was continued by Dr W D Johnson of Batavia, Dr A B Raffl of Syracuse, Dr L F Simpson of Rochester, Dr L F O'Neill of Auburn, Dr A K Bates of Auburn, Dr W L Wallace of Syracuse, Dr E C Foster of Penn Yan.

ALBERT M CRANCE, M D, *Secretary*

---

## STEUBEN COUNTY

The Medical Society of the County of Steuben held its annual meeting at the Wagner Hotel, Bath, N Y, on November 9th

The election of officers for the year 1928 results as follows

President, G E Taylor, M D, Hornell, N Y  
Vice-President, G M Parkhurst, M D, Bath, N Y

Secretary and Treasurer, W S Cobb, M D, Corning, N Y

# NEWS NOTES

## CLINTON COUNTY

The Annual Meeting of the Clinton County Medical Society was held on October 18, at the City Hall, Plattsburgh, N Y, and was preceded by a luncheon at the Witherill House at which sixteen were present Dr G R Allen, the President, called the meeting to order at two o'clock

Roll call showed the following present Drs C R Hutchins, W F Brown, L G Barton, Jr, E S McDowell, G R Allen, E W Sartwell, L G Barton, F K Ryan, W H Ladue, H C T McDowell, Leo F Schiff, A A de Grandpre, T A Rogers, A Schneider, I A Rowlson, W U Taylor, S Mitchell, also Dr E R Baldwin and Dr F F Finney

The following officers for 1928 were duly elected

President, E S McDowell, M D  
 Vice-President, B R Webster, M D  
 Secretary, Leo F Schiff, M D  
 Treasurer, F D Ryan, M D  
 Censors Drs C M Burdick, I A Rowlson,  
 R S Macdonald  
 Delegate Leo F Schiff, M D  
 Alternate, A Schneider, M D

Dr Schiff reported for the Milk Commission that one meeting had been held for organization at which time it was decided to add two members to the Commission, that Dr Allen had appointed Drs Mitchell and Taylor as additional members, and that the Commission had appointed a Veterinarian and an Examining Physician, and was now awaiting the application of producers to have their milk certified

Dr Schiff addressed the meeting in regard to the post-graduate instruction about to be undertaken by the Society in cooperation with the Committee of the State Society on Public Health and Medical Education

The following scientific program was carried out

- 1 Septicemia, Dr F K Ryan, Plattsburgh, N Y
- 2 Septic Endocarditis, Dr S Mitchell, Plattsburgh, N Y
- 3 The Interpretation of Tuberculous Foci in X-Ray films, and their Significance, illustrated by lantern slides, X-ray films, and pathological specimens, by Dr E R Baldwin, Saranac Lake, N Y

## QUEENS COUNTY

A regular meeting of the Medical Society of the County of Queens was held at Eagle Palace, on Tuesday evening, October 25, at 8 30 P M, President Joseph S Thomas, M D, in the chair, and 54 members present Seven new members were elected

Dr F G Riley, chairman, reported for the Committee on Graduate Education that the course of Dr Mencken was over subscribed, that there was one vacancy in the course of Drs Steffen and Smith, and that relative to the course in Cardiology by Dr Keet it had not been made clear that the course was being paid for by the Public Health Committee

The scientific session opened with a paper by Dr Walter A Bastedo, M D, on "Points in Gas-

tro-intestinal Therapeutics," in which he reviewed the common conditions with which doctors have to deal, such as dieting, constipation, flatulence, putrefaction

The paper was discussed by Drs McMahon, Thomas, Barber, Sowers and Lint

Dr Martin L Sowers presented a paper on "Mastoiditis" with lantern slide illustrations In the course of the presentation anatomical specimens of mastoids were presented showing the anatomy of various types of operation

The paper was discussed by Dr Harriet White and Dr Bastedo

A collation was served at the close of the meeting

E E SMITH, M D, *Secretary*

## MADISON COUNTY

The Madison County Society met on November first, at Oneida, N Y

The following officers were elected  
 President, Dr J D Boyd, Chittenango  
 Vice-President, Dr S H Raymond, Cazenovia  
 Secretary, Dr D H Conterman, Oneida

Treasurer, Dr Lavinia R Davis, Oneida  
 Delegate to State Society, Dr E L Finley, Oneida

The following resolutions were passed

- 1 That Madison County Medical Society desires and recommends that vaccination against

smallpox be made compulsory for all school children of the State of New York

2. The Madison County Medical Society favors County Health Organizations, but does not believe that the present County Health Unit plan as advocated would be suitable or ideal for Madison County, without further consideration of the matter

President E L Finley gave a résumé on past, present and future activities of the Society, with special reference to the practice of public health and civic medicine

Dr Edwin MacFarland of Utica gave an interesting paper on "Methods of Urological Examination"

D H CONTERMAN, M D, *Secretary*

---

## SARATOGA COUNTY

The annual meeting of the Saratoga County Medical Society was held at the Homestead Sanatorium, Middle Grove, N Y, November 2

Following a bounteous dinner given by the Board of Managers and Dr Asa Dimock, Superintendent, the scientific program was given

Dr George Beilby, Albany, N Y, gave an interesting lecture on Goitre.

The following officers were elected

President, Thomas J Goodfellow, M D, Saratoga Springs, N Y

Vice-President, F F Gow, M D, Schuylerville, N Y

Secretary, R B Post, M D, Ballston Spa, N Y

Treasurer, John W Mabey, M D, Mechanicsville, N Y

Delegate to N Y Convention, Earl King, M D, Saratoga Springs, N Y

Alternate Delegate, J MacElroy, M D, Jonesville, N Y

Committee Minora, E J Callahan, M D, Schuylerville, N Y, G Scott Towne, M D, Saratoga Springs, N Y, D Mauro, M D, Mechanicsville, N Y, M J Cornthwaite, M D, Ballston Spa, N Y, L A. Parmenter, M D, Corinth, N Y

Censors, A W Porter, M D, F F Gow, M D, George Fish, M D

The applications of Dr Mark D Duby, Schuylerville, N Y, and Dr Asa Dimock, Middle Grove, N Y, having been received and passed by the Board of Censors, they were elected to membership in Saratoga County Medical Society

The report of the special committee to investigate defects among school children was read and approved

R. B Post, M D, *Secretary*

---

## GENEVA ACADEMY OF MEDICINE

The third annual dinner meeting of the Geneva Academy of Medicine was held in the Hotel Seneca, Geneva, on the evening of Wednesday, November 9th. The attendance was 190 physicians and surgeons from Geneva and the surrounding territory, some coming from the neighboring county secretaries, and some from Syracuse, Rochester and Buffalo

The program of the meeting was opened by Dr Harry Trick of Buffalo, President-elect of the Medical Society of the State of New York. He brought the greetings of the State Society and congratulations on the excellent support

shown by the members of this Academy, the latest one to be formed in the State

Dr George W Crile of Cleveland, Ohio, gave an address on the "Clinical Aspects of the Goiter Problem." The discussion was opened by Dr Martin B Tinker, of Ithaca, and Dr Donald Guthrie, of Sayre, Pa. The discussion was continued by Dr W D Johnson of Batavia, Dr A B Raffl of Syracuse, Dr L F Simpson of Rochester, Dr L F O'Neill of Auburn, Dr A K Bates of Auburn, Dr W L Wallace of Syracuse, Dr E C Foster of Penn Yan.

ALBERT M CRANCE, M D, *Secretary*

---

## STEBUEN COUNTY

The Medical Society of the County of Steuben held its annual meeting at the Wagner Hotel, Bath, N Y, on November 9th.

The election of officers for the year 1928 resulted as follows

President, G E Taylor, M D, Hornell, N Y  
Vice-President, G M Parkhurst, M D, Bath, N Y

Secretary and Treasurer, W S Cobb, M D, Corning, N Y

Dr A H Paine of Rochester, presented a paper on "The Management of Urological Problems Commonly Encountered"

Dr E W Phillips of Rochester, discussed the "Surgical Treatment of Thoracic Diseases"

The Society appointed a committee to confer with the Board of Supervisors regarding the enlargement of the nursing service of the County

I W BREWER, M D, *Secretary*

## JEFFERSON COUNTY

The annual meeting of the Medical Society of Jefferson County was held on November 10, at which time the following officers were elected

President, Byron Haskin, M D

Vice-President, W W. Hall, M D

Secretary, Walter S Atkinson, M D

Treasurer, J E McAskill, M D

Censors W A Vincent, M D, H A Hoyt, M D, H C. Montgomery, M D, L L Sampson, M D

Dr Charles Dwight Reid gave an address on "Common Orthopedic Conditions," dealing with the subject in a most instructive and practical manner

Our retiring President, Dr Olin, gave an address dealing with the ethical side of the practice of medicine and emphasizing the importance of cooperation between physicians (This address

will be printed in a future issue of this JOURNAL—Editor's note)

The Public Relations Committee is to be appointed, the first duties assigned to them are to investigate the matter of County Health Unit and to confer with the Public Health Committee and another committee appointed by the staff of the Mercy Hospital, to formulate a plan for a hospital or pavilion connected with one of our present hospitals to take care of all communicable diseases in the city and county

Dr Ebba Dederer, School Physician for Watertown, was transferred from the Ulster County Medical Society to our Society

The meeting was very well attended and several out of town guests were present

WALTER S ATKINSON, M D, *Secretary*

## KINGS COUNTY MEDICAL SOCIETY

The monthly meeting of the Medical Society of the County of Kings was held on Tuesday evening, November 15th

The scientific part of the program was of great interest and consisted of two addresses (1) "Development of Neurology in America—Personal Reminiscences" by Charles Loomis Dana, M D, LL D Dr Dana, from his rich experience in the field of neurology, reminisced about the many neurologists with whom he has collaborated during his many years of active work

The second paper of the evening "A Neurologist Looks at Neurology" by Joseph Collins, M D, was an equally interesting presentation of

the subject of neurology, and was on a par with Dr Collins' many books with which the medical profession is, of course, familiar Rarely has a medical society had an opportunity for the historical, scientific and literary review of any branch of medicine such as was provided for the Medical Society of the County of Kings in its meeting devoted to Neurology

The November meeting being the meeting for the nomination of officers, a full set of officers were nominated

The President, Dr Thurston S Welton announced the anonymous gift of \$2,500 a year toward the payment of an increase in salary to the Librarian, Mr Charles Frankenberger

# MEDICAL WARES

## CASTILE SOAP

Soap is the principal commercial product that is prescribed and used by physicians and hygienists, and soap, water and elbow grease form the triad of cleansing agents which keep the world clean and healthy

The ordinary fats or oils which are used in soap making are composed principally of three fatty acids 1, stearic, which melts at  $157^{\circ}\text{F}$ , and predominates in tallow; 2, palmitic, which melts at  $143.6^{\circ}\text{F}$ , is the principal one of palm oil and is a liquid at ordinary temperatures, and 3, oleic, which is the principal constituent of linseed oil

Soaps partake largely of the physical properties of the fatty acids of which they are made A soap made from tallow is hard, and one from linseed oil is soft. Hardness and softness also depend largely on the alkali that is used, soda producing a hard soap and potash one that is soft The oleic acid soaps, such as those made from cocoanut oil usually lather easily, while those made from stearic acid produce lather that lasts well Shaving soaps are therefore usually made from cocoanut oil and tallow

Soap is made by two processes The cold process consists in mixing the fat and alkali at a temperature just sufficient to melt the fat, and letting the mixture stand for a few days while the chemical action takes place All the materials including the glycerine, water and impurities remain in the soap that is made by the cold process Most commercial soap is made by the hot process, in order to recover the glycerine, which is a valuable by-product In the hot process the mixture of fat and alkali is boiled, and then salt is added Since most soap is insoluble in salt water, it floats to the surface leaving the glycerine in solution below it Marine soap, which forms a lather with sea water, is made from cocoanut oil, whose soap is soluble in salt water to a greater extent than other soaps

Soaps that float have had minute particles of air incorporated into their mass by agitation The liquid soaps used in wash basins are perfumed solutions of soap in water

Common laundry soaps contain a large proportion of rosin, whose chief constituent, abietic acid, unites with the alkali to form soap

Transparent soaps are made either by adding glycerine, or by dissolving the soap in alcohol which is then removed The cheaper grades are made transparent by the addition of five or ten per cent of sugar

Soap has great power of combining with other substances, such as antiseptics, coloring matter and scouring material, and of masking their physical characteristics The adulteration and imitation of the better grades of soap are therefore easy and are done on an extensive scale Soap may be made from almost every kind of fat or oil of animal or vegetable origin Purifying processes and the use of perfumes to mask unpleasant odors make possible the utilization of the grease derived from dead animals and decaying garbage The gross appearance of soaps is no guarantee of their purity or quality, but a chemical analysis will reveal adulterations and impurities

Since soap is a variable product, it is desirable that a standard form should be recognized Such a standard is set by the United States Pharmacopoea The pharmacopoea lists the standard soap under the technical term, *sapo*, and under the common term, soap It further adds the descriptive term, "olive oil castile soap" The specifications are that this soap shall be made from pure olive oil to which sodium hydroxide is added in an amount just sufficient to combine with the fatty acids and yet leave no free alkali This soap has a faint odor and taste which are pleasant and characteristic, and is the soap which is commonly used in dentifrices and tooth pastes, for in them purity and high qualities are peculiarly desirable

The term castile soap has been applied to pure olive oil soap for hundreds of years, and a soap containing any other fatty acid than that from olive oil is not castile soap according to the Pharmacopoea Physicians ordering castile soap for any purpose will do well to specify the U S P product

The Pharmacopoea lists a preparation of olive oil soap called *linimentum saponis*, which contains 60 parts of soap in 1,000 parts of a solution of camphor This is the liniment which was kept in our grandfather's medicine closets and was called *opodeldoc*—a term invented by that scientific charlatan, Paracelsus, early in the sixteenth century

The Pharmacopoea also lists *saponis mollis*, soft soap which is made from potassium hydroxide and cotton seed oil, but linseed oil was formerly used This is the soap that is used in making *linimentum saponis mollis*, which is a 65 per cent solution of soap, and is the preparation that was formerly called tincture of green soap

# THE DAILY PRESS

## FAITH HEALING IN THE CHURCH

The daily papers of New York City give half an inside column once or twice a week to the faith-healing services conducted in the Calvary Baptist Church on West 57th Street, New York City, but they seldom give the reports space on the front page. The condition of the patients is shown by the following extracts from the *New York Herald Tribune* of November 8

A young Italian girl, accompanied by her weeping mother, limped out of the anteroom, apparently no more improved in her paralysis than before the stocky gentleman had anointed her thin pinched legs, supported by braces

A woman with goiter showed no visible relief though the preacher and his assistant had commanded the goiter to go. A crippled woman was apparently no better able to walk after the contact with oil and bay rum. A flush had not filled the cheeks of a consumptive

On the other hand, a man, who said he was a Jew, and had come to the preceding service to be healed, testified that he had "forgotten about his kidneys." His complexion looked yellow and diabetic

A man wearing smoked glasses walked up and said that his left eye pained him. The assistant made him close its lid, then applied bay rum and oil, which he continually shook in the small bottle

"What about that pain now, brother? Praise God, eh brother. It's gone, isn't it?"

The man blinked vigorously for a moment then smiled and went back to his chair. Another woman with similar pain in her left eye, she said, came up to be relieved in the same manner. Then she announced that she could not kneel, which she did with apparent ease after application of oil

Another woman came up to relate that her ton-

sils were troubled by a swelling. The assistant applied oil on her neck and told her that the pain had gone. Next came a crippled woman who admitted no relief after treatment and limped out of the room, though Dr. Straton, who laid his hands on her shoulders, assured her that she was all right

A little girl with black hair and eyes, red from weeping, bit her lip in pain and grief while her Italian mother stood and wept and the healer applied oil

The assistant with the bottle poured oil and bay rum into the ear of a man who said his memory was poor and that he was hard of hearing. He put his mouth close to the man's ear and spoke

"You hear me better now, don't you?" he asked

The sufferer grinned spaciouly and nodded, then shouted "Amen"

Then came the woman with a goiter—then the consumptive

"No tuberculosis germ can stand in the presence of God," the assistant said, applying oil on the young man's flushed cheeks

The public health aspects of the healing services were discussed in the *New York Times* of November 12, by Dr. Louis I. Harris, Commissioner of Health of the City of New York, who is quoted as saying

"Dr. Straton assured me that it was not his purpose to do anything to conflict with the public health laws or public health interest. He said that in a limited sphere he thought he could render a service in helping to heal certain types of cases that would be influenced by spiritual support and encouragement

"Dr. Straton said that he gave no promise to any person suffering from disease that he could assure him health. He stated that he would go more fully into his relation with the medical profession and public health in his sermons"

## DEADLY HUNTERS

While hunting is death to animals, it is also death to men. The *New York Herald Tribune* of November 28 prints a report of the Conservation Department of New York State that twenty-eight persons have been killed by hunters and seventy-one wounded in New York State during the month of October 15 to November 15, when deer shooting was allowed. The report says "This was the largest number killed or injured

with the exception of 1925 when the total number of accidents was 115, with twenty-nine killed and eighty-six injured

"Deer hunting annually takes an average of twenty lives, the department declared in a statement given out today. Fourteen hunters were killed by their own guns and twelve were killed by guns in the hands of companions

"Seventeen met injury while shooting game

birds and animals by the discharge of their own guns and thirty hunters were hurt by the discharge of guns in the hands of their companions. One guide, mistaken for a deer, was killed.

"In 1924 the shortest list of hunting accidents was noted, when the woods were closed for two weeks because of the danger of fire. This year it was reported more hunters were abroad than in any other year.

Comparing New York's hunting death rate with that of Pennsylvania, the *New York Times* of November 29 says editorially:

"Pennsylvania, with a smaller population than New York, always has more casualties. In 1925 forty-five hunters were killed and about two hundred were wounded. In 1923 the number killed was fifty-three. But Pennsylvania is the greatest

hunting state in the union for variety of game. In the latter year the game bag included 6,452 deer, 500 bears and 6,049 wild turkeys."

An effective remedy for the slaughter of both men and animals is the substitute of the camera for the gun. Camera hunting has all the thrills of gun shooting, and it preserves the actual game alive while at the same time the animals and birds disport themselves in pictures and on the movie screen at the will of the hunter. No one who has experienced the thrill of hunting with a camera will resume the gun.

Some of the leading physicians of New York, Drs. F. R. Oastler and Harlow Brooks, for example, delight to entertain and instruct their medical brethren with picture clinics of their experiences in camera hunting.

---

### HAIR WORMS AND SEX STUDIES

Every rural school boy will tell you that horsehairs can turn into worms, for he has seen them wriggle around in horse troughs. Every rural physician who has a reputation for knowledge in natural history is a center of information to whom natural curiosities are brought for identification, and among the specimens which he gets in the fall are hair worms looking like black horsehairs. These worms are parasites in grasshoppers, and when they are liberated, their eggs are laid on grass and are eaten by other grasshoppers. The hair worm is the subject of an article in the *New York Sun* of November 29, describing the experiments of scientists of the United States Department of Agriculture regarding the determination of sex. The article states:

"A few hairworm eggs are not necessarily immediately fatal to the grasshopper, but when as many as fifty are swallowed and hatched it results in the death of the grasshopper. In trying to discover the lowest number likely to cause the

death of a grasshopper these researchers grow the eggs and feed them.

"There is no apparent escape from the conclusion that we are dealing with cases where environment is a sex 'determining' factor, a factor which becomes potent not during the early embryology of the animal, but after a well developed, highly differentiated larva has been formed.

"The three scientists hope their discovery will lead other experimenters to follow what they consider a most interesting and suggestive line of physiological research with the hope of learning more of the nature and origin of sex."

It has long been known that environment may determine the sex of a newly hatched worm, or insect. The queens of honey bees are produced by special kinds of food fed to the newly hatched larvae, and the sex of pomace flies may be directed by the manner in which the young are reared. But the researchers have not reached the stage in which the conclusions may have a practical application to higher animals.

---

### SYNTHETIC CHEMISTRY

This year is the centenary of the birth of Marcelin Berthelot, the father of Synthetic Chemistry. The *New York Tribune* of November 12, in an editorial appreciation of his work, says:

"For Liebig's habit of taking everything apart to see what atoms were in it, Berthelot substituted the process of putting atoms together to see what new things he could make. Unlike many discoverers, he knew full well the power of his new tool. 'The domain where synthetic chemistry exercises its creative power,' he wrote, 'is vaster than that which Nature has actually realized'—a prediction amply sustained, for the compounds since produced by chemical creation far exceed those found in Nature.

"Berthelot's first success at putting two atoms

with another two to make a novel foursome was an imitation of the ants. These insects manufacture, as close contact with them proves all too well, an acrid liquid which pupils of Liebig had already analyzed and named formic acid. Berthelot put together carbon monoxide gas and water to make this same acid, thus dispensing with the ant. Next he made alcohol out of water and ethylene, ignoring the yeast. Finally, he manufactured acetylene from its two inorganic elements, carbon and hydrogen. In themselves these creations mattered little, no more than adding a column of figures. It is the idea that counts. Chemists found that they, too, can play at creation. If Nature lacks what they want they can make it for themselves."

# OUR NEIGHBORS

## THE BACTERIOPHAGE

The October issue of *California and Western Medicine* contains an article on the bacteriophage which will be of interest to the general reader. The following extracts show what the bacteriophage is and tell the theory of its action.

"The discovery of bacteriophagy by d'Herelle in 1916 marks the beginning of one of the most important epochs in the history of bacteriology, not only because of its theoretical, but probable practical bearing. In August of that year there came to the hospital of the Pasteur Institute an adult suffering with a severe form of Shiga dysentery. During the course of the patient's illness d'Herelle made bouillon cultures of the stools daily. These cultures were incubated overnight and filtered through a Chamberland filter. A few drops of the filtrate was then added to a young bouillon culture of dysentery bacilli and the mixture placed in the incubator. Throughout the course of the disease the tubes so prepared yielded normal cultures of dysentery bacilli. One morning, however, the tube prepared on the previous day was found to be sterile. At the same time it was learned that the condition of the patient had greatly improved. The sterile tube was filtered and a few drops of the filtrate was added to a fresh suspension of dysentery bacilli and placed in the incubator. In about ten hours this tube also became limpid. A few drops of the filtrate of this lysed culture induced complete clarification of the third suspension, and so on indefinitely in series. In other words, the lytic principle was regenerated with the dissolution of each culture.

"On spreading a suspension of Shiga bacilli, to which a little of the filtrate had just previously been added, on an agar surface, d'Herelle noted after incubation the presence of a number of small, circular, clear areas in an otherwise uniform turf of bacterial growth. These d'Herelle ascribed to the deposition of corpuscles of the lytic agent present in the mixture which he had spread on the agar surface. He believed that the original corpuscles deposited on the surface had parasitized and dissolved the growing bacteria in their immediate vicinity and that the clear areas actually represented colonies of the lytic corpuscles. The number of the clear areas varied with the quantity of the filtrate added to the bacterial suspension. D'Herelle concluded that the phenomenon must be due to an invisible parasite of the bacteria and he accordingly gave it the name of 'bacteriophage'.

"Following the isolation of a bacteriophage active on dysentery bacilli, d'Herelle isolated in

rapid succession races active on a number of other species of bacteria, including *B. coli*, *B. typhosus*, *B. paratyphosus* A and B, *B. gallinarum*, *Pasteurella bovisepitica*, *Pasteurella pestis*, *Vibrio cholerae*, etc. Races active on staphylococcus and streptococcus and several other species have been added by other investigators.

"With few exceptions these races have all been isolated from the feces of man and animals, particularly from convalescents, and from water and soil. Indeed, according to d'Herelle every animal and every man harbors a bacteriophage in symbiosis with *B. coli* or other species of the normal intestinal flora. In the event of an invasion by a pathogenic bacterium the bacteriophage normally present gradually acquires a virulence for the invader and brings about its elimination after the virulence has attained a certain level.

"It is generally held now that the bacteriophage is of corpuscular nature. Indeed its size has been estimated to be about 20 to 30 units. According to one investigator it is of about the same dimension as the virus of vaccinia and of rabies. The bacteriophage is more resistant to heat than are vegetative forms of bacteria. The temperature of inactivation seems to be related to the degree of virulence. Some impairment of the activity is said to appear at 45°C, but at about 75°C complete inactivation results in thirty minutes, whatever the race or degree of virulence. It is also more resistant to chemical agents than are vegetative forms of bacteria. It may retain its activity in filtrates over a period of years, though the corpuscles are said to diminish appreciably during this time. Injected repeatedly into the animal body the bacteriophage gives rise to an antiphagic serum, which is capable of exercising a definite inhibiting action on the phenomenon.

"According to d'Herelle, the outcome of a bacterial infection probably depends on the rapidity with which the bacteriophage naturally present in the intestine acquires a virulence for the invading organism. Under favorable conditions a rapid adaptation on the part of the bacteriophage results in an early elimination of the pathogenic organism after only a few mild symptoms, or no symptoms at all. Under less favorable conditions the acquired virulence appears later and there is a proportionate delay in the abatement of the disease symptoms. At any rate, a potent bacteriophage is said to make its appearance simultaneously with the onset of convalescence. Moreover the bacteriophage does not remain con-

(Continued on page 1396, adv. riv.)

# Maltine

WITH  
COD LIVER OIL

*—a preparation  
preferred by many  
physicians  
to cod liver oil  
alone*

As a disease preventive and as an agent in the treatment of pulmonary affections, strumous and tubercular diathesis, and rickets, the value of cod liver oil is firmly established. In combination with Maltine, cod liver oil is easy of administration and assimilation. And Maltine adds the essential proteid elements of barley, wheat and oats. Its mineral salts and soluble vegetable albuminoids are valuable aids to normal growth and health.

Maltine with Cod Liver Oil is readily digested. It is a pure and dependable preparation free from the unpalatable qualities of plain cod liver oil. When the digestive processes are weakened and nourishment is impeded, Maltine with Cod Liver Oil may be safely prescribed. As an adjunct to the dietary of infants and children, it is a food that may be generally used to advantage.

mumized had contracted the disease, despite the fact that it was prevalent in Indo-China In 1925 Le Louet reported that the immunization had been continued and that the incidence of barbone had been reduced to practically nothing

"Up to 1924 da Costa Cruz prepared as a member of the Institute Oswaldo Cruz, at Rio de Janeiro, about 10,000 ampouls for distribution to hospitals and physicians in Brazil There have been to his knowledge only two exceptions to the uniformly good results reported Indeed, the promptness with which the patient responds to the treatment is a matter of astonishment to the physicians The patients as a rule enter on convalescence within twenty-four to forty-eight hours after the bacteriophage has been administered In Rio de Janeiro this method of treatment is now routinely employed in bacillary dysentery

"In the preparation of the bacteriophage suspension destined for therapeutic use, d'Herelle emphasizes that 'it is absolutely indispensable that the bacteriophage be of maximum virulence for the bacterium upon which it is to act' It is furthermore important that the filtration be made through a candle of known efficiency and that the tubes be inspected for freedom of bacterial growth before use It is administered by mouth About two cubic centimeters of the filtrate is given in a half glass of water Twelve hours later a second dose may be administered The ingestion of the bacteriophage is harmless, whatever the dose, either for a normal man or a patient suffering from some other disease In other words, there are said to be no contraindications

"In the treatment of colon infections of the urinary tract the bacteriophage is administered subcutaneously and by instillation into the bladder Subcutaneously it may be administered in doses of about 2 cc at an interval of about twenty-four to forty-eight hours, but not more than two doses should be administered in this way Bladder instillations should be made at the same time with about a 1:10 dilution of the bacteriophage in physiological saline. The instillations may be repeated, but if a therapeutic effect does not appear within a week it is probable that none will be realized No reactions are said to follow the administration of the bacteriophage"

fined to the intestinal tract, but, as has been shown by several investigators, may pass into the circulation and so reach affected tissues lying outside of the alimentary tract. In other words, although this latent defense resides in the intestinal flora, once aroused, its activities may extend to distant tissues in the body.

"Moreover, according to d'Herelle, the virulent bacteriophage eliminated in the feces of the convalescent may be in turn ingested by normal individuals living within the zone of an epidemic and so convey a timely protection to otherwise susceptible individuals. In other words, he holds that this particular type of immunity, like the disease itself, is infectious in character. The epidemic ceases at the moment when all susceptible individuals harbor a bacteriophage active for the causative organism of the epidemic. Either the bacteriophage has acquired a virulence in the body of the individual who harbors it, or this individual has been 'contaminated' by a bacteriophage which has acquired a virulence in another individual for the specific bacterium involved.

"With these introductory remarks let us proceed to a consideration of the possible prophylactic and therapeutic value of the bacteriophage.

"In 1919 d'Herelle reported significant results following the immunization of chickens against fowl typhoid during the course of a natural epizootic. About 1600 chickens, including 100 chickens already sick, were inoculated. Each animal received 0.5 cc of a virulent bacteriophage subcutaneously.

"Buffaloes have a highly fatal hemorrhagic septicemia known as barbone. The high mortality among these important beasts of burden entailed a great economic loss to the country. d'Herelle states that during an epizootic which he witnessed in one of the provinces, 10,000 of the 30,000 buffaloes in the region succumbed to the disease. The mortality approached 100 per cent. The Government therefore placed a number of animals at the disposal of d'Herelle and Le Louet for investigation. They first undertook to determine the value of the bacteriophage as an immunizing agent against experimental barbone. The bacteriophage employed was a highly virulent race which d'Herelle had recovered from the feces of a buffalo which passed unaffected through the previous epizootic. The bacterium employed to test the immunity was a highly virulent organism which killed the control animals within twenty-four hours.

"According to d'Herelle, Le Louet later, as Inspector-General of the Veterinary Service of Indo-China, proceeded to carry out the immunization on a large scale. In September of 1923 he reported that none of the 12,000 buffaloes im-

(Continued on page 1399, adv xv)

(Continued from page 1398, adv xvi)

cut off the heads of four criminals and splinters into their eyes at the same instant as the fatal one that had entered the of the king

several generations ago, in France, a celebrated savant, author of a work on the effects of guano, desired to prove his theories by actual practice. For the purpose of carrying out his proposition, he requested the Minister of Justice in Paris to allow him to try an experiment on a criminal condemned to death. The Minister consented, and turned over to the physician a murderer of distinguished rank. The Minister informed this unfortunate that several persons being interested in his family had pressed upon the judge not to require of him the usual means of execution. His sentence, he was told, was therefore changed. "But," continued the physician, "you shall be bled to death within the precincts of your prison, your dissolution will be gradual, and free from pain." The criminal submitted to his fate, thinking that his family would be less disgraced through this procedure, and considered it a special favor to be allowed to die in this manner. He was accordingly made ready for the experiment. By conducting affairs cleverly he was readily made to believe that his veins had been opened and that his blood was flowing freely, whereas, he had only but gently pricked on the skin, and small quantities of water were placed about him, to regulate the flow of blood. Within a few hours the man was dead, and the doctor was satisfied with such a practical confirmation of his theories. Thus a criminal condemned to death consented to die in a manner that was both useful to society and more pleasing to himself than had it been the hands of the executioner.

In the United States there has been at various intervals earnest and serious discussion of this question. Among the most notable was that at a meeting of the Tri-State Medical Association, held at Peoria, Ill., October 3, 1893. At this time Dr. John S. Pyle read a paper entitled "Plea for the Appropriation of Criminals, Condemned to Capital Punishment, to the Experimental Physiologists."

Several years later Mr. Rowlen introduced to the Senate of Ohio a bill proposing the vivisection of capital criminals (House Bill No. 135, 41st General Assembly, Regular Session.)

## THE ETHICS OF MEDICAL PUBLICITY

Publicity of the work of hospitals and dispensaries often brings upon the institutions the imputation that they may not be entirely ethical in their statements and claims. It also raises the

# VIVISECTION OF CRIMINALS

It is an old suggestion, sometimes put in practice, that murderers be subjected to vivisection by scientists in place of being put to death in the usual ways. The Illinois Medical Journal for November has a historical article on the subject by Dr. Edward Podolsky of Brooklyn, which the following extracts are taken from.

"The desire for medical truth had manifested itself very early in human experience. Theoretical utilization of murderers was commenced in early Egypt. Somewhat later, Ptolemy Philadelphus attained notice by placing at the disposal of the scientists of Alexandria criminals convicted for the worst crimes. The rise of Alexandria to a medical center in ancient times was a great measure due to this institution.

"Several centuries later Herophilus, the Thessalian and pupil of Praxagoras of Cos, and later Diocles of Carytus, the first of the Hellenistic school to distinguish himself as an anatomist, began to dissect criminals. These were taken from the prisons by royal permission. Erasistratus, Herophilus carried on his anatomical researches on the bodies of living criminals on a large scale, it being reputed that Herophilus alone dissected over six hundred criminals in these studies. The ancient apologist for human vivisections of Herophilus and Erasistratus used to say that it is not to be regarded as an act of cruelty, as some persons suppose, but, to seek for the remedies of an immense number of innocent persons in the sufferings of criminals."

The next important stage in the history of criminal vivisection was enacted during the Middle Ages. In Montpellier and in other French cities, at this time, physicians vivisected criminals in their search for medical truth. In the Italian cities of Florence, Venice, and Pisa, the practice was sanctioned and practiced. In the Criminal Archives of Florence Professor Brocchi has discovered the fact that during the reign of Cosimo de' Medici, condemned criminals were from time to time sent to the studios of Pisa, there to be anatomized. After the date 1570 no more cases occur in the Archives. In all, thirteen criminals were delivered over to specific scientific research. During part of this period the great Vesalius and his pupil Fallopius were carrying on their researches in anatomy and lecturing on this science.

"After this period the vivisection of criminals diminished to a very small scale. Now and then a vivisection was performed for some definite purpose. Such was the case when Henry II of France was mortally wounded by a splinter from a spear which had entered below his visor, pierced his eye, and the surgeons, for the purpose of discovering the probable injury done to the eye, performed a vivisection.

rise of desire or judgment on the part of the man.

If the paragraph in the code of ethics relating to the matter of advertising were abolished tomorrow, and every practicing physician or institution allowed to state in the form of advertisement his opinion of himself and his skill in handling of disease, just what would be the effect to the public? There is no doubt that the law with the largest appropriation for advertising and the best advertising manager, regardless of his skill or ability, would become the most prevalent in practice.

The public might with profit observe the following general rule or truism. The doctor who, in hope for gain, will violate the provisions of the code of ethics which govern his relationship to his fellow practitioners, will from the motive in all probability violate those provisions which govern his relationship to his patient. Shall we adhere to the code or shall it be brushed?"

## NARCOSAN IN DRUG ADDICTION

The treatment of drug addicts by a preparation called narcosan was featured in the daily press of New York City from December 14, 1926 to the middle of January, and an adverse judgment regarding its efficiency was published on page 144 of this JOURNAL for February 1, 1927.

A condemnatory notice of narcosan was printed by the *Journal of the American Medical Association* for December 18, 1926, page 2097. The wide publicity given to the new treatment led intelligent inquirers to ask why the medical profession does not investigate narcosan and its virtues. The November issue of *Colorado Medicine*, the organ of the Medical Society of Colorado and Wyoming, reports a trial of the treatment. The account says:

"The composition of narcosan as stated by Lambert and Tilney is a solution of lipoids together with non-specific protein and water soluble amines. The theory of the action of narcosan in the body is that narcotics such as morphine call forth in the body certain protective substances to neutralize them. If the narcotics are suddenly withdrawn and not given, these neutralizing substances are themselves toxic to the body. The lipoids in narcosan neutralize these toxic substances in place of the narcotics."

On admission to the hospital the patient was given 1½ to 2 grams of calomel followed in three hours by 1 ounce of magnesium sulphate. Soon as he was thoroughly purged the administration of narcosan was begun.

"The treatment followed at the Colorado Psychopathic Hospital prior to the use of narcosan

## SALIPYRIN "Riedel"

is a chemical combination of antipyrin and salicylic acid. The therapeutic effects of both these components are preserved, although modified by close chemical union and in a very great degree deprived of the dangers of mechanical mixtures.

Salipyrin is distinguished from other salicylates by the comparative

freedom from ill-effects (absence of free antipyrin) and prompt antipyretic and sedative action.

**INDICATIONS** Influenza, Colds, Catarrh of the Nose and Throat, Rheumatism, Neuralgia, Alcoholic Excess, Pleurisy, Dysmenorrhea, Metrorrhagia, Vaginitis, etc. If given early in the attack, Salipyrin generally succeeds in aborting colds.

Salipyrin is supplied in powder form and as **SALIPYRETS** in tablets of 7½ each.

Approved by the Council on Pharmacy and Chem. of the American Medical Association for inclusion with N. N. R.

question whether or not an institution properly give out information that would be on the unethical and the advertising, if it issued by a private practitioner. The ethical advertising has sometimes involved hospital connected with medical schools. It entered into the criticism of the management of the Well Pay Clinic, which was the subject of a editorial in this JOURNAL of February 1, 1922 has recently developed in an acute form: Vanderbilt Hospital of the Vanderbilt School of Medicine in Nashville, Tennessee, and discussed in the November issue of the *Journal of the Tennessee State Medical Association*. The news item described the action of the Nashville Academy of Medicine and quoted the following letter which was sent to the Dean of the School of Medicine:

"The Nashville Academy of Medicine has taken official notice of certain articles occurring at various times in the lay press of this city relative to the special facilities enjoyed by the Vanderbilt Hospital both as to the personnel of the hospital and by virtue of its intimate association with the Vanderbilt School of Medicine. All the articles referred to are those occurring in the *Nashville Banner* of October 9, 1922, the *Nashville Tennessean* of October 16, 1922.

"These articles seem to bear the stamp of authoritative promulgation. It appeared to the body that these publications were improper wording and their implications. The matter referred to the Board of Councillors, composed of the ex-presidents of the society, for consideration. The Board of Councillors decided unanimously that the articles were unethical and of a bad taste. A motion was passed asking the Nashville Academy of Medicine to address a letter to you through its secretary embodying that position."

Commenting on the newspaper article the JOURNAL says editorially:

"They do not lay claim to any new or startling discovery that is of any practical usefulness to humanity. They do emphasize the degree of competence of persons engaged in work in the medical school and hospital, and it is clear that the articles are calculated to impress the public with the idea that a very superior professional service is to be obtained in the hospital."

The editorial closes with the following observations:

"The public and certainly the lay press are under a false impression as to what the principles of medical ethics really are. The principles of medical ethics constitute the greatest protection to the public against fraudulent and misleading claims by doctors or charlatans concerning their services or their remedies. There is not a provision in medical ethics that hinders in the least the

## THE ACTION OF THE SPLEEN

The November issue of the *New Orleans Medical and Surgical Journal* has an editorial on the spleen, and after referring to its function in making and destroying blood, it further enumerates the uses of the organ as follows

"The spleen plays an important part in immunity. It is instrumental in antibody formation, it takes toxins, and it has an elective affinity for bacteria. Also it is a most important organ in the reticulo-endothelial system. Certain cells of the spleen are markedly phagocytic, which may play some part in its immunological activities. Further immunological functions are not proven in human beings, but are assumed from animal experimentation. The spleen probably helps to inhibit the growth of tumors. Splenic implants of tumor growths grow much less readily than elsewhere in the body, and likewise tumor implants grow very much more readily in the splenectomized animal than in the non-splenectomized. It plays some rôle in aiding natural immunity to tuberculosis. Tuberculosis of the spleen as a primary condition is rare. As a secondary manifestation it is rarely found until the body is overrun by the infection. Animals with large spleens are difficult to infect by injections of the bacillus of tuberculosis, as, for example, the cat and the dog. On the other hand, animals with small spleens are readily infected, such animals being the well-known laboratory mammals, rabbits and guinea-pigs. That the spleen plays any part in digestion or metabolism is a mooted question. Probably it has something to do with the metabolism of iron."

## BASIC SCIENCE EXAMINATIONS

The question of examinations in the basic medical sciences was discussed by Dr W C Woodward, executive secretary of the Bureau

## Vegex Concentrated Yeast Extract

Strongest and most palatable form of yeast for health, fermentation removed

Richest known source of B vitamins

Meat-like flavor, no meat, tasty, instant bouillon, broth, etc.

Adds vitamin B, iron and growth-promoting proteins in child feeding, expectant and nursing mothers

VEGEX is used by physicians in arranging diets in gastro-intestinal, diabetic and nervous disorders, post-operative cases, liquid diet in general practice.

VEGEX is the physicians dependable source of the B vitamins, and contains Dr Goldberger's "P-P" factor

VEGEX is accepted for advertising in the *Journal of the American Medical Association*

## Also Vegex Candy

This Candy is investigated and accepted for advertising in the *Journal of the American Medical Association*, as

### "A Candy Physicians Can Recommend for Children"

Contains the B vitamins, proteins and mineral salts from brewer's yeast, whole milk solids, Air-Line Honey and the vitamins from cod liver oil

No Yeast Nor Oil Taste, Delicious

Vegex Candy serves as sole source of these vitamins in feeding tests for good growth and reproduction

Samples and literature to physicians and hospitals

Address

of Legal Medicine and Legislation of the American Medical Association on November 18th, at the Annual Conference of State Secretaries and Editors of State Medical Journals

The results of the examinations in the State of Washington, one of the five States having the basic science law, and stated editorially in the November issue of *Northwest Medicine* as follows

"The Basic Science Act, which passed the last session of the Washington legislature chiefly as a result of efforts on part of the Public Health League, has been in effect a sufficient length of time to demonstrate results already accomplished and to suggest what may be anticipated from it in the future. Its essence is the requirement that all persons caring for the sick must pass an examination at Olympia in the subjects of anatomy, physiology, chemistry, pathology and hygiene, which are recognized as the foundation of all methods of treating human ailments

"Reports from the Department of License at Olympia show that medical applicants are successfully passing in these subjects, with a fair percentage of osteopaths, Chiropractors, sanipractors and other forms of drugless healers evidently have been conspicuous by their absence. In fact, from some of the recognized legal forms of cultism there have not appeared or late a sufficient number of applicants for license to make necessary an examination. It is notable that there has come about a marked reduction in the number of healers of various sorts who have been flocking to Washington recently in large numbers. There is every reason to believe that the administration of this Act will have a permanent effect in purifying the various classes of practitioners who in the future will attend the sick in this State."

(Continued from page 1401, adv xix)

consisted in the immediate withdrawal of all narcotics, the use of bicarbonate of soda to combat any tendency toward acidosis, detoxification by the daily use of high colonic irrigations and the control of restlessness by the use of continuous baths at a temperature of 98 to 100 degrees Fahrenheit

"Publicity attendant upon the introduction of the narcosan treatment resulted in twenty-two of the twenty-four cases entering the hospital thoroughly convinced of the efficacy of the drug. In view of the well known suggestibility of these patients, we feel that this has been an important factor in the subjective reactions to treatment

"All of the patients treated showed the characteristic withdrawal phenomena to a greater or less degree. Seventeen showed nausea and vomiting and they and the remaining seven showed restlessness, irritability, abdominal cramps and pains in the legs. Eleven patients stated that they were definitely relieved by narcosan injections, seven stated that they could see no influence on their immediate withdrawal symptoms and the remaining six were definitely opposed to the use of narcosan, feeling that it added to their discomfort

"The influence of narcosan on the amount of sleep obtained by the patients undergoing treat-

ment has been stressed in the report previously mentioned and careful observations were in this regard. The average amount of sleep obtained during the first 96 hours under treatment was 16 hours or an average of 4 hours per night. During the second period of 96 hours an average of 24 hours' sleep was obtained or an average of 6 hours per night. During the remainder of their stay in the hospital the patients averaged 6½ hours' sleep per night.

"Contrasted with this sleep record is the record of those patients treated in the Columbia Psychopathic Hospital before narcosan was introduced. During the first 96 hours this group averaged 10 hours of sleep, an average of 5 hours per night. In the second 96 hours, an average of 25 hours' sleep was obtained or 6¼ hours per night. During the remainder of their stay in the hospital an average of 7 hours' sleep per night was obtained

"The follow-up reports have not been completed. Of the twenty-four patients treated, nine had permanent addresses. Information regarding the remaining group was obtained from their associates. Information has not been obtained on six. Of the eighteen about whom information has been obtained eleven have returned to the use of drugs. Of the control group there was no information on eight, but four were known to be off of drugs
